## ABSTRACT

Although the role of the transcription factor NF- $\kappa$ B in intestinal inflammation and tumor formation has been investigated extensively, a physiological function of NF- $\kappa$ B in sustaining intestinal epithelial homeostasis beyond inflammation has not been demonstrated. Using NF- $\kappa$ B reporter mice, we detected strong NF- $\kappa$ B activity in Paneth cells, in '+4/+5' secretory progenitors and in scattered Lgr5<sup>+</sup> crypt base columnar stem cells of small intestinal (SI) crypts. To examine NF- $\kappa$ B functions in SI epithelial self-renewal, mice or SI crypt organoids ('mini-guts') with ubiquitously suppressed NF- $\kappa$ B activity were used. We show that NF- $\kappa$ B activity is dispensable for maintaining SI epithelial proliferation, but is essential for *ex vivo* organoid growth. Furthermore, we demonstrate a dramatic reduction of Paneth cells in the absence of NF- $\kappa$ B activity, concomitant with a significant increase in goblet cells and immature intermediate cells. This indicates that NF- $\kappa$ B is required for proper Paneth versus goblet cell differentiation and for SI epithelial homeostasis, which occurs via regulation of Wnt signaling and Sox9 expression downstream of NF- $\kappa$ B. The current study thus presents evidence for an important role for NF- $\kappa$ B in intestinal epithelial self-renewal.

**KEY WORDS:** NF- $\kappa$ B, Intestine, Paneth cells, Goblet cells, Stem cells, Epithelial self-renewal, Mouse

## INTRODUCTION

The single-layered epithelium of the small intestine (SI) self-renews approximately every 5 days and thus displays the fastest turnover in mammalian tissues. The continuous and intense self-renewal of the various intestinal epithelial cell (IEC) types is guaranteed by specialized stem cells. These reside in a particular niche, the

so-called crypts of Lieberkühn, located at the bottom of the villus, which itself constitutes the differentiated compartment of the SI (reviewed by Barker et al., 2008; Clevers, 2013; Gehart and Clevers, 2019). Both compartments are connected by a clearly restricted transition zone composed of transit-amplifying (TA) progenitor cells (reviewed by Barker et al., 2008, 2010; Carulli et al., 2014). The villus consists of absorptive enterocytes and of three types of secretory cell types: the enteroendocrine, tuft and goblet cells (Barker et al., 2010). A fourth cell type of the secretory lineage, Paneth cells, is found in crypts, intermingled with the highly proliferative intestinal stem cells (ISCs), also denominated crypt base columnar stem cells (CBCs) (Clevers and Bevens, 2013). Maintenance of CBCs and differentiation of Paneth cells strongly rely on active canonical Wnt signaling (Pinto et al., 2003; van Es et al., 2005; Fevr et al., 2007; Farin et al., 2012), which is potentiated by the R-spondin receptor Lgr5 (leucine rich repeat containing G protein coupled receptor 5) specifically expressed on CBCs (Barker et al., 2007; Koo and Clevers, 2014).

So far, the role of the transcription factor NF- $\kappa$ B in intestinal homeostasis has been studied in the contexts of inflammation and of tumorigenesis (reviewed by Pasparakis, 2009; Ben-Neriah and Karin, 2011; Taniguchi and Karin, 2018). IEC-specific deletion of either NF- $\kappa$ B subunits or components of the upstream IKK (I $\kappa$ B kinase) complex, but also constitutively elevated IKK/NF- $\kappa$ B activity in the intestinal epithelium, consistently resulted in local infiltration of immune cells and inflammation (such as in inflammatory bowel disease), increased IEC apoptosis and tissue damage (Chen et al., 2003; Greten et al., 2004; Nenci et al., 2007; Steinbrecher et al., 2008; Guma et al., 2011; Vlantis et al., 2011; Shaked et al., 2012; Schwitalla et al., 2013; Vereecke et al., 2014; Vlantis et al., 2016; Mikuda et al., 2020). Although tumor formation was also observed in IKK/NF- $\kappa$ B knockout (KO) mice to some degree, high incidence of colitis and spontaneous inflammation-associated tumor formation (colitis-associated cancer) was significantly enhanced in mice with constitutively active IKK/NF- $\kappa$ B in IECs (Shaked et al., 2012; Mikuda et al., 2020). Furthermore, it has been shown that NF- $\kappa$ B is required for mucosal innate immunity, barrier functions, and immune resistance to the intestinal microbiome, as well as for the formation of Peyer's patches, which are part of the gut-associated lymphoid tissue in the small intestine (Schmidt-Ullrich et al., 2001; Yilmaz et al., 2003; Zaph et al., 2007; Pasparakis, 2008). These studies suggest that intestinal NF- $\kappa$ B activation must be a well-balanced and strictly controlled process.

We have previously shown that NF- $\kappa$ B controls fetal hair follicle induction and participates in a significant manner in the regulation of the postnatal hair cycle, which is responsible for periodic renewal of hair follicles (Schmidt-Ullrich et al., 2006; Zhang et al., 2009; Krieger et al., 2018). Similar to intestinal epithelial self-renewal, the hair cycle strictly depends on actively cycling Lgr5-positive stem cells located in the bulge region of the hair follicle (reviewed by

Fuchs, 2007; Blanpain and Fuchs, 2014; Hsu et al., 2014). We have demonstrated that in hair follicles NF- $\kappa$ B directly regulates the expression of markers that are essential for stem cell maintenance and activation (Zhang et al., 2009; Tomann et al., 2016; Krieger et al., 2018). Here, in the SI epithelium we observed strong NF- $\kappa$ B activity in Paneth cells, in +4/+5 secretory progenitors and occasionally in CBCs. This prompted us to examine more closely the role of NF- $\kappa$ B in IEC self-renewal. The results of the current study were obtained from a mouse model with ubiquitously suppressed NF- $\kappa$ B activity (here referred to as  $\Delta N$ ; Schmidt-Ullrich et al., 2001). Simultaneous suppression of NF- $\kappa$ B in IECs and surrounding tissues did not result in inflammation, which is observed persistently in epithelial-specific NF- $\kappa$ B/IKK KOs (see above and Pasparakis et al., 2002; Stratis et al., 2006; Grinberg-Bleyer et al., 2015), and did not show any changes in IEC proliferation or apoptosis. However, our data reveals a previously unknown role for NF- $\kappa$ B in Paneth versus goblet cell fate decisions.

## RESULTS

### Strong NF- $\kappa$ B activity is observed in murine SI in Paneth cells and secretory progenitors at position +4/+5

To analyze NF- $\kappa$ B activity in the small intestine under physiological conditions, NF- $\kappa$ B reporter mouse lines using either  $\beta$ -galactosidase ( $\kappa$ -Gal; Fig. 1A) or EGFP ( $\kappa$ -EGFP; Fig. 1B,C) expression as a read-out for NF- $\kappa$ B activity were examined 8–12 weeks after birth. In the adult murine SI, strong  $\beta$ -galactosidase or EGFP expression was confined to the crypts (Fig. 1A,B). Specificity of the signal was determined using  $\kappa$ -EGFP; $\Delta N$  mice, in which NF- $\kappa$ B activity is ubiquitously suppressed and in which EGFP expression was absent in SI crypts (Fig. 1B). NF- $\kappa$ B activity in SI crypts was further validated by *in situ* hybridization (ISH) using a riboprobe of *Nfkb1a*, a bona fide target gene of NF- $\kappa$ B that encodes I $\kappa$ B $\alpha$  (inhibitor of NF- $\kappa$ B  $\alpha$ ) (Le Bail et al., 1993). As expected, endogenous *Nfkb1a*

mRNA expression was only detected in SI crypts (Fig. S1A, upper panel, control).

Co-staining of EGFP with Alcian Blue, the Paneth cell marker lysozyme or the ISC marker Olfm4 (olfactomedin 4; see also van der Flier et al., 2009) in the SI of  $\kappa$ -EGFP mice identified SI crypt cells with NF- $\kappa$ B activity mainly as Paneth cells, but also as cells at position +4/+5 and occasional CBCs (Fig. 1C). Cells at position +4/+5 above the SI crypt have previously been identified as potential secretory precursors (Stamatakis et al., 2011; van Es et al., 2012; Buczacki et al., 2013; Tetteh et al., 2015). These results suggest a physiological function for NF- $\kappa$ B in Paneth cells and in progenitors.

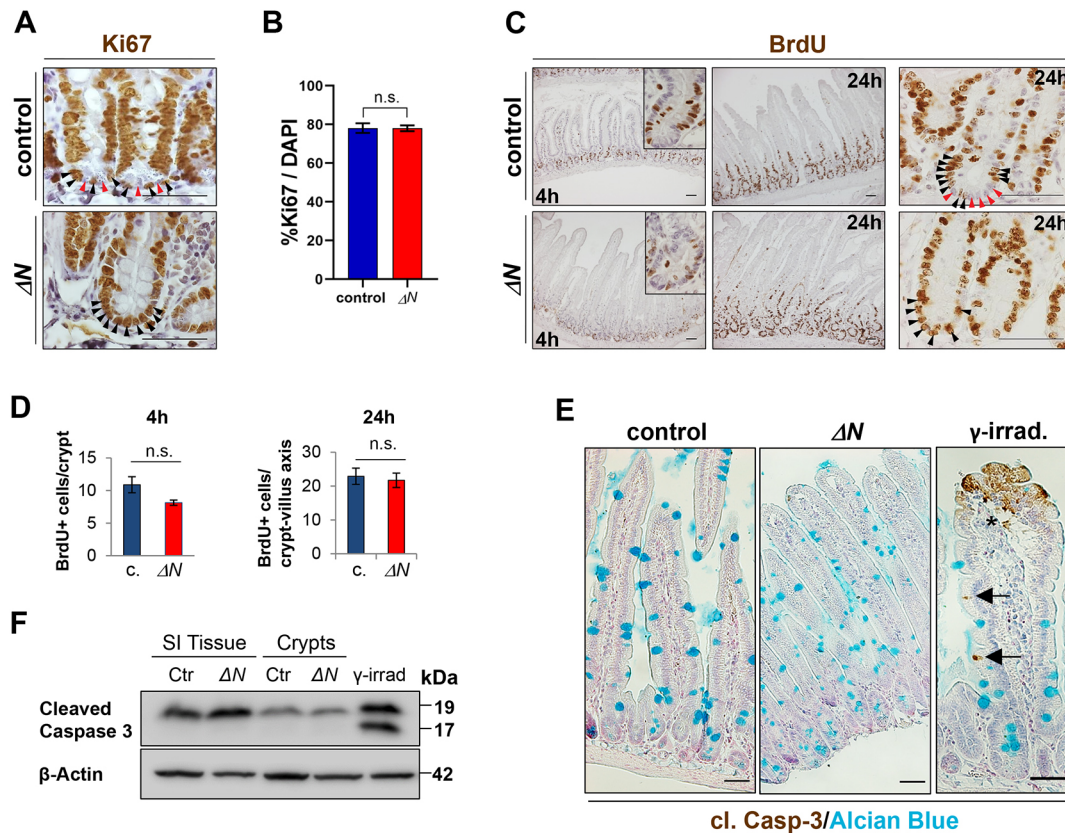

### IEC proliferation and cell death remain unaltered in $\Delta N$ mice

To investigate further the functions of NF- $\kappa$ B in the SI epithelium, mice with ubiquitous suppression of NF- $\kappa$ B activity ( $\Delta N$ ) or mice with IEC-restricted NF- $\kappa$ B inhibition (*villin*<sup>CRE</sup>*flxed*  $\Delta N$ ; hereafter referred to as *Villin- $\Delta N$* ) were examined. Suppressed NF- $\kappa$ B activity in  $\Delta N$  mice was verified by loss of *Nfkb1a* mRNA expression (Fig. S1A). More importantly, in  $\Delta N$  and *flxed*  $\Delta N$  mice the truncated form of the NF- $\kappa$ B inhibitor I $\kappa$ B $\alpha$  ( $\Delta N$ ) was integrated in-frame into the  $\beta$ -catenin (*Cttnb1*) locus, which does not impair expression and activity of the  $\beta$ -catenin protein (Fig. S1B,C; Schmidt-Ullrich et al., 2001). Thus, the phenotype observed here is a result of ubiquitous suppression of NF- $\kappa$ B activity.

Among others, NF- $\kappa$ B can regulate cell proliferation and death. Ki67 staining showed an altered distribution of proliferating cells in SI crypts of  $\Delta N$  mice (Fig. 2A). In contrast to controls, all crypt base cells were positive for Ki67 and may correspond to TA cells that migrate into the crypt and/or other immature cell types (Fig. 2A). To analyze the proliferation rate further, we used 5-bromo-2'-desoxyuridine (BrdU) treatment for either 4 h to detect alterations in the cell cycle or for 24 h to reveal migration defects within the intestinal epithelium (Fig. 2C). Quantitative analysis of

**Fig. 1. Cell type-specific NF- $\kappa$ B activity in crypts of the small intestine.** (A) Technovit section of X-gal-stained PSIs of  $\kappa$ -Gal reporter mice ( $n=3$ ). Inset shows magnification with X-Gal-stained cells in the bottom of the crypts and in +4/+5 position (black arrowheads). Arrowheads indicate specific X-Gal staining in crypts, asterisks diffuse, nonspecific staining. Scale bars: 50  $\mu$ m (main panel); 10  $\mu$ m (inset). (B) Indirect immunofluorescence using an anti-EGFP antibody on PSI sections of  $\kappa$ -EGFP and  $\kappa$ -EGFP; $\Delta N$  mice (representative of  $n=3$  mice per group). Yellow arrowheads indicate EGFP expression/NF- $\kappa$ B activity, asterisk marks nonspecific staining in villi. Scale bars: 50  $\mu$ m (far left and far right); 20  $\mu$ m (middle). (C) EGFP IHC [DAB (brown) alone and DAB plus Alcian Blue staining; left panels] and immunofluorescence co-staining of EGFP with anti-lysozyme or anti-Olfm4 antibodies on PSI sections of  $\kappa$ -EGFP mice ( $n=3$ ). Black arrows and yellow arrowheads point to Paneth cells; black or red arrowheads indicate EGFP expression/NF- $\kappa$ B activity in ISCs, mainly in +4 and +5 positions. Scale bars: 20  $\mu$ m. Nuclear counterstain: DAPI (blue).

**Fig. 2. Unaltered IEC proliferation and cell death rate in  $\Delta N$  mice compared with controls.** (A) Anti-Ki67 antibody staining on PSI sections of  $\Delta N$  and control mice indicating proliferative cells.  $n=3$  per group. (B) Quantification of average numbers of Ki67<sup>+</sup> cells as a percentage of total DAPI-stained cells.  $n=3$  per group,  $n>20$  crypts per mouse. (C) Anti-BrdU antibody staining on PSI sections of  $\Delta N$  and control mice indicating BrdU incorporation 4 or 24 h after injection. Insets show magnified images of crypts. In A and C, in crypts of controls proliferating ISC (black arrowheads) are intermingled with Paneth cells (red arrowheads). (D) Quantification of BrdU<sup>+</sup> cells per crypt (4 h) and per crypt-villus axis (24 h) in control or  $\Delta N$  mice.  $n=3$  per group,  $n\geq 20$  crypts per mouse. (E) Representative IHC images of anti-cleaved caspase 3 and Alcian Blue staining on PSI sections of  $\Delta N$  and control ( $n=3$  per group) mice, and of a tissue sample of  $\gamma$ -irradiated control mice (see Kolesnichenko et al., 2021). Black arrows point to caspase 3-positive (apoptotic) cells in villi of irradiated controls. Asterisk indicates nonspecific staining due to handling. (F) Analysis of cleaved caspase-3 protein expression. Total PSI and PSI crypt whole-cell extracts of control and  $\Delta N$  mice ( $n=3$  per group) were used for SDS-PAGE western blotting.  $\beta$ -Actin was used as loading control. Scale bars: 50  $\mu$ m (A,C); 200  $\mu$ m (E). In B,D, error bars represent s.e.m.; n.s., not significant (unpaired Welch's  $t$ -test).

SI sections stained with either anti-Ki67 or anti-BrdU antibodies did not show any alteration in numbers of BrdU- or Ki67-positive cells in  $\Delta N$  crypts compared with controls (for 4 h BrdU:  $P=0.1$ ; for 24 h BrdU:  $P=0.38$ ; for Ki67:  $P=0.96$ ; Fig. 2B,D). Similar to Ki67 staining, in controls we observed BrdU-positive CBCs adjacent to post-mitotic Paneth cells whereas in  $\Delta N$  mice crypts were entirely occupied with BrdU-positive cells (Fig. 2C, right panels, 24 h). These data demonstrate that suppression of NF- $\kappa$ B activity does not change the overall proliferation rate in the intestinal epithelium.

A recent study found that mice with intestinal epithelial knockout of the IKK subunit IKK $\gamma$  (also known as NEMO) or subunits of NF- $\kappa$ B showed a significant increase in apoptosis of IECs, including Paneth cells (Vlantis et al., 2016). However, neither terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) nor cleaved caspase 3 staining showed an elevated number of apoptotic cells in the SI epithelium or in crypts of  $\Delta N$  mice compared with controls (Fig. S2A, Fig. 2E,F). Importantly, no increase in inflammatory cytokines was observed in intestines of  $\Delta N$  mice (Fig. S1D), in contrast to mice with constitutively elevated NF- $\kappa$ B activity in IECs (*I $\kappa$ B $\alpha$ <sup>IEC-KO</sup>*) (Fig. S1E), which exhibited increased inflammation, proliferation and apoptosis (Mikuda et al., 2020). Analyses of selected inflammatory bowel disease markers that depend on NF- $\kappa$ B activity also showed that in comparison with

*I $\kappa$ B $\alpha$ <sup>IEC-KO</sup>* mice and controls, expression of these NF- $\kappa$ B targets was significantly reduced or absent in  $\Delta N$  mice (Fig. S1F) (Mikuda et al., 2020).

### Increase in goblet cells in the SI of $\Delta N$ mice

Alcian Blue staining, which detects acidic mucopolysaccharides, revealed a dramatic increase of Alcian Blue-positive cells in SI, particularly in the crypts of  $\Delta N$  and *villin- $\Delta N$*  mice compared with controls (Fig. 3A). This was observed in all three major segments of the small intestine: the duodenum [proximal small intestine (PSI)], jejunum [medium SI (MSI)] and ileum [distal SI (DSI)] (Fig. 3A; Fig. S2B). Quantification by counting Alcian Blue-positive cell numbers/crypt unit verified this finding (1.9-fold increase; Fig. 3B). Note that we did not observe any abnormalities related to inflammatory processes in the SI of *villin- $\Delta N$*  mice (data not shown) and increased goblet cell numbers were also never reported in any of the mice with IEC-specific deletion of IKK/NF- $\kappa$ B. Alcian Blue usually stains mature goblet cells, but also immature intermediate Paneth/goblet cell precursors, which prompted us to analyze goblet cell markers. mRNA expression of the goblet cell markers *Gob5* (*Clea1*) and *Muc2* was significantly increased in  $\Delta N$  mice, whereas expression of *Klf4* (Krüppel-like factor 4) remained similar to controls (Fig. 3C). Accordingly, *Muc2* protein expression

**Fig. 3. Increased numbers of goblet cells in  $\Delta N$  mice.** (A) IHC on PSI sections of control,  $\Delta N$  and *Villin- $\Delta N$*  mice ( $n=3$  per group) stained with either Alcian Blue alone or together with an anti-lysozyme antibody. Scale bars: 50  $\mu\text{m}$ . Insets show magnified images of crypts. (B) Quantification of the average number of Alcian Blue-positive cells per crypt.  $**P<0.01$ ,  $***P<0.001$  (unpaired Welch's *t*-test). Error bars represent s.e.m.  $n=5$  per group,  $n=50$  crypts per sample. (C) qRT-PCR for mature goblet cell markers *Gob5*, *Muc2* and *Klf4* using RNA from PSIs of  $\Delta N$  and control mice ( $n=5$  per group).  $*P<0.05$ ,  $**P<0.01$  (multiple *t*-test with Bonferroni correction). (D) Immunofluorescence using anti-Muc2 and anti-E-cadherin (cadherin 1) antibody staining on sections of PSI of control and  $\Delta N$  mice ( $n=3$  per group). Nuclear counterstain: DAPI (blue). Scale bars: 50  $\mu\text{m}$  (A,D, main panels); 10  $\mu\text{m}$  (insets).

was also elevated in SIs of  $\Delta N$  mice (Fig. 3D). *Muc2* and *Gob5* are markers for mature goblet cells and *Klf4* controls goblet cell fate decisions but is not required for final differentiation (Katz et al., 2002; Garg et al., 2007; Ghaleb et al., 2011; Pellegrinet et al., 2011). These results suggest that *Klf4* may act upstream of NF- $\kappa$ B activation in secretory cell fate decisions, and confirm increased amounts of goblet cells in SIs and possibly the presence of immature intermediate Paneth/goblet cell precursors in the crypts of  $\Delta N$  mice.

#### Loss of Paneth cells in SI crypts of $\Delta N$ mice

Anti-lysozyme immunofluorescence staining on sections of the SI (PSI, MSI and DSI) showed no more than one or two Paneth cells per crypt in  $\Delta N$  and *Villin- $\Delta N$*  mice compared with the usual three or four Paneth cells (per visual field) in controls (Fig. 4A; Fig. S3A). Hematoxylin & Eosin staining on PSI sections of  $\Delta N$ , *Villin- $\Delta N$*  and control mice, as well as *in situ* hybridization using a riboprobe for cryptdin-1 (*Defa1*) or immunofluorescence staining and western blotting using an antibody against the Paneth cell marker *Mmp7* confirmed this finding (Fig. 4A; Fig. S3B-D). Loss of Paneth cells was particularly drastic in duodenal crypts (PSI) of  $\Delta N$  and *Villin- $\Delta N$*  crypts ( $4.1\pm 0.3$  for control,  $1.5\pm 0.1$  for  $\Delta N$  and  $1.4\pm 0.3$  cells for *Villin- $\Delta N$* ), but was somewhat less pronounced in jejunum (MSI) and ileum (DSI) (Fig. 4A; Fig. S3A). The overall reduction in Paneth cells in the absence of NF- $\kappa$ B activity was about 73% compared with controls (Fig. 4B,C).

The loss of Paneth cells in  $\Delta N$  mice was confirmed by significantly diminished mRNA expression of mature Paneth cell markers lysozyme and cryptdin-1 as shown by qRT-PCR of RNA isolated from the SI of  $\Delta N$  and control animals (Fig. 4D). Increased goblet cells and loss of Paneth cells suggest that NF- $\kappa$ B may play a role in cell fate decisions that are made in specialized secretory progenitors, which are thought to be located above the stem cell/Paneth cell zone (for a review, see Tetteh et al., 2015). We thus examined RNA expression of the basic helix-loop-helix (bHLH) transcription factor *Math1* (*Atoh1*, atonal homolog 1), *Gfi1* (growth factor independent 1), the Notch-ligands Delta-like 1 and 4 (*Dll1* and *Dll4*) and the bona fide Notch target *Hes1* (hairy and enhancer-of-split 1), as well as *Spdef* (SAM pointed domain containing ets transcription factor) (Fig. 4E). Whereas *Math1*, *Gfi1*, *Dll4* and *Spdef* expression remained unaltered, the secretory progenitor markers *Dll1* and *Hes1* were significantly reduced in  $\Delta N$  mice compared with controls (Fig. 4E). Our results indicate that the formation of *Math1*- and *Gfi1*-positive secretory progenitors is not affected by the absence of NF- $\kappa$ B activity in the intestinal epithelium. This suggests that early secretory precursor cells are generated in the absence of NF- $\kappa$ B activity, but subsequent differentiation into Paneth cells is interrupted in favor of goblet cells.

#### NF- $\kappa$ B is required for maturation of Paneth cells

Paneth and goblet cells derive from a common secretory lineage progenitor that, among others, expresses *Spdef* (Gregorieff et al.,

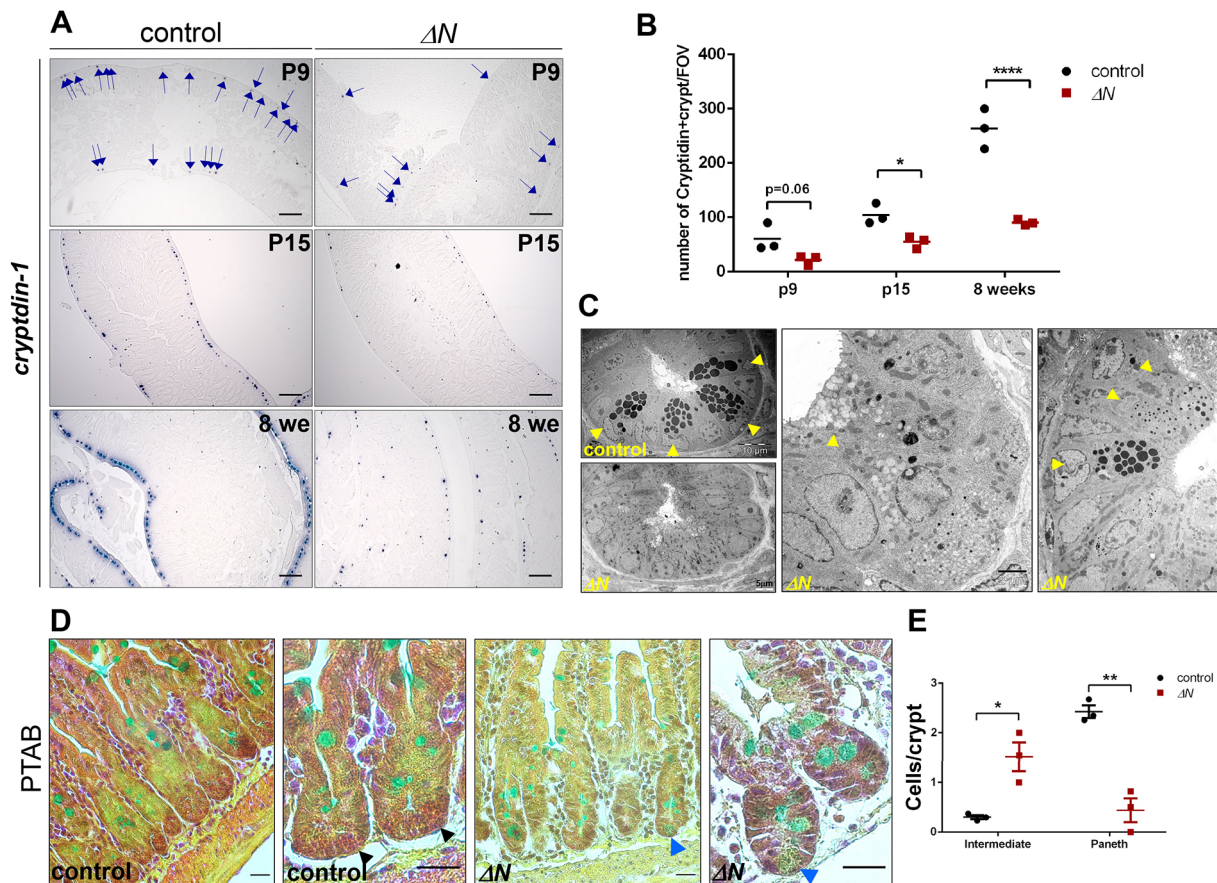

**Fig. 4. Strongly reduced numbers of Paneth cells in crypts of  $\Delta N$  mice.** (A) Top: Immunofluorescence using anti-lysozyme antibody staining on sections of PSI of control,  $\Delta N$  and *Villin- $\Delta N$*  mice ( $n=3$  per group). Error bars represent s.e.m.

2009; van Es et al., 2012; Buczacki et al., 2013; Basak et al., 2014) (reviewed by Koo and Clevers, 2014). In *Spdef*<sup>-/-</sup> mice, terminal differentiation of Paneth and goblet cells is impaired (Gregorieff et al., 2009; Noah et al., 2010). Surprisingly, expression of *Spdef* was not altered in  $\Delta N$  mice (Fig. 4E, and see below). Furthermore, *Spdef*<sup>-/-</sup> mice showed normal NF- $\kappa$ B activity in the intestinal epithelium, indicating that both transcription factors are regulated independently (Fig. S4A). Although both *Spdef* and NF- $\kappa$ B are involved in Paneth cell differentiation, loss of Paneth cells seemed much more dramatic in the absence of NF- $\kappa$ B activity than in *Spdef*<sup>-/-</sup> mice (Fig. 4; for comparison, see Gregorieff et al., 2009).

Differentiated Paneth cells are first observed around 7-10 days after birth (Bry et al., 1994). However, maturation is not completed until 15-17 days after birth (Bry et al., 1994; Clevers and Bevins, 2013). We thus performed comparative studies of  $\Delta N$  and control mice at postnatal day (P) 9 and P15 and at 8 weeks of age (adulthood) (Fig. 5A,B). EGFP expression analysis in  $\kappa$ -EGFP reporter mice affirmed that NF- $\kappa$ B was active in crypts at the chosen time points (Fig. S4B). In  $\Delta N$  mice, ISH using a riboprobe for

cryptdin-1 revealed a reduced number of cryptdin-1-positive crypts already at P9 prior to final differentiation/maturation, compared with controls (about 50%; Fig. 5A). Upon final differentiation at P15 and in adulthood (8 weeks), the number of cryptdin-1-positive crypts remained strongly decreased in  $\Delta N$  mice compared with controls (Fig. 5A). Quantification of these results and antibody staining for lysozyme at P15 and 8 weeks of age supported this finding (Fig. 5B; Fig. S4C). Of note, not only was the number of crypts containing Paneth cells reduced, but also the number of Paneth cells per crypt (Fig. 4C). Furthermore, whereas in controls the number of cryptdin-1-positive crypts increased about threefold between P15 and 8 weeks, in  $\Delta N$  mice the increase was not statistically significant (Fig. 4B).

To characterize further the observed crypt-based secretory cell types in  $\Delta N$  mice, we visualized crypts by transmission electron microscopy (TEM) comparing SI tissue from  $\Delta N$  and control mice at 8-12 weeks of age (Fig. 5C). TEM images confirmed the lack of mature Paneth cells in most crypts of  $\Delta N$  mice (Fig. S4D). Paneth cells in controls typically showed large dark secretory granules (Fig. 5C). In contrast, in most crypts of  $\Delta N$  mice we observed cells

**Fig. 5. NF- $\kappa$ B is required for differentiation and maturation of Paneth cells.** (A) ISH on PSI sections of control and  $\Delta N$  mice ( $n=3$ /group) at P9, P15 and 8 weeks of age using a riboprobe for cryptdin-1. Error bars represent s.e.m.

with an altered morphology, containing granules that displayed reduced electron density (Fig. 5C). These cells strongly resembled the immature intermediate cells previously described in a mouse model in which Paneth cells were specifically deleted by cell-lineage ablation (Garabedian et al., 1997), but also in *Spdef*<sup>-/-</sup> mice that lack mature goblet and Paneth cells (Gregorieff et al., 2009; Noah et al., 2010). As we did not detect any mature goblet cells in TEM images of  $\Delta N$ -positive crypts, the aberrant Alcian Blue-positive cells observed in crypts of  $\Delta N$  mice are likely to correspond rather to intermediate cells. For further analysis of these intermediate cells, we also performed phloxine/tartrazine-Alcian Blue (PTAB) co-staining. In mature Paneth cells, phloxine/tartrazine typically stain the granular, lysozyme-containing vacuoles red, as is seen in controls (Fig. 5D). In contrast,  $\Delta N$  crypts only revealed cells with greenish granules that lacked lysozyme (Fig. 5D). Quantification of PTAB staining confirmed that intermediate cells were present only at low levels in  $\Delta N$  mice (Fig. 5E). Together, these data suggest that immature intermediate cells accumulate in crypts of  $\Delta N$  mice and that the few Paneth cells that do form in  $\Delta N$  mice do not appear to mature properly.

Note that numbers of another secretory cell type in the IEC, enteroendocrine cells, were not affected by the absence of NF- $\kappa$ B activity (Fig. S5A). In line with this, mRNA expression of the

enteroendocrine cell markers chromogranin A and somatostatin was similar to controls (Fig. S5B).

#### Altered expression of Wnt-dependent CBC markers in SIs of $\Delta N$ mice

NF- $\kappa$ B activity was also observed in a subset of CBCs (Fig. 1). To address whether suppressed NF- $\kappa$ B activity also affects CBCs, the expression of various ISC markers was analyzed. We did not observe any changes in mRNA expression of Wnt-independent CBC markers, such as the pan stem cell marker *Olfm4*, or *Smoc2*, *Lgr1*, *Tert* and *Hopx* (Fig. S5C,D). However, mRNA and protein expression of the Wnt-dependent CBC markers *Lgr5*, *Ascl2*, *Edn1*, *Cnd1* and *Tnfrsf19* (also known as Troy) was significantly reduced in crypts of  $\Delta N$  mice compared with controls (Fig. S5E-G). The expression of *Ephb3*, *Msi1* and *Prom1* was unaltered (Fig. S5E), but these latter three factors are not only expressed in CBCs, but also in secretory precursors (Battle et al., 2002; Kim et al., 2017), which suggests that only *Lgr5*<sup>+</sup> CBCs are diminished in the crypts of  $\Delta N$  mice. In contrast to  $\Delta N$  mice, mice with constitutively elevated NF- $\kappa$ B activity in the IECs (*I $\kappa$ B $\alpha$* <sup>IEC-KO</sup>) showed a significant increase in Wnt activity and *Lgr5*<sup>+</sup> CBCs in organoids (Mikuda et al., 2020). Although *Ascl2* has also been described as a potential direct NF- $\kappa$ B target gene before (Vlantis et al., 2011), these results indicate that

Wnt signaling is diminished and maintenance of *Lgr5*<sup>+</sup> CBCs is at least in part dependent on NF- $\kappa$ B activity.

Paneth cells provide niche factors, such as Wnt ligands, but also express the Notch ligand *Dll1*, and both Notch and Wnt signaling are required for CBC maintenance (Pinto et al., 2003; van Es et al., 2005; Fevr et al., 2007; Farin et al., 2012; for a review, see Gehart and Clevers, 2019). We observed reduced *Hes1* and *Dll1* expression in the crypts of  $\Delta N$  mice (Fig. 4E), indicating reduced Notch signaling in the SI crypts of  $\Delta N$  mice. Finally, the *Ki67*<sup>+</sup>/*Lgr5*<sup>+</sup> cell ratio was significantly higher in  $\Delta N$  mice compared with controls (Fig. S5H), confirming a decrease in *Lgr5*<sup>+</sup> cells in the crypts of  $\Delta N$  mice. Together, these results strongly suggest alterations in the cell composition of the SI stem cell niche in  $\Delta N$  mice.

### Wnt3 rescues growth of $\Delta N$ crypt organoids (mini-guts), but not Paneth/goblet cell fate decisions

To explore further the relevance of NF- $\kappa$ B in Paneth versus goblet cell fate decisions, SI organoid growth and cell composition was examined.

Organoids were generated either directly from PSI crypts of  $\Delta N$  and control mice or from single EGFP-positive CBCs obtained from *Lgr5-EGFP*; $\Delta N$  ( $\Delta N$ ) and control mice (*Lgr5-EGFP*; Barker et al., 2007) by fluorescence-activated cell sorting (FACS). In contrast to normal *in vivo* proliferation rates observed in the SI epithelium of  $\Delta N$  mice (Fig. 2A,B), the *ex vivo* ability to culture organoids obtained either from SI crypts of  $\Delta N$  mice or from isolated *Lgr5*-positive CBCs from *Lgr5-EGFP*; $\Delta N$  mice was virtually absent in culture medium without Wnt3 (ENR; Fig. 6A,C; Fig. S6A,F): Less than 10% of SI crypts isolated from  $\Delta N$  mice generated organoids after 4–8 days of culture (Fig. 6A), which might be a consequence of Paneth cell ablation in  $\Delta N$  intestinal epithelia. This is in line with previous studies that showed that in the absence of Paneth cells, no organoids are formed (Sato et al., 2011). However, supplementation of organoid culture medium with Wnt3 ligand (WENR) restored  $\Delta N$  organoid growth and *Ki67* expression after 5, 7 or 8 days of culture, whereas organoid growth of controls was not affected [Fig. 6B,C; Fig. S6A,B,F (Fig. S6B shows EdU incorporation)]. As expected, expression of the CBC markers

**Fig. 6. In crypt organoids, suppression of NF- $\kappa$ B activity results in strongly reduced growth, but also an increase in goblet cells and a loss of Paneth cells.** (A) Quantification of viable organoid formation at days 4 and 8 after isolation of PSI crypts from control or  $\Delta N$  mice ( $n=4$  per group). \*\*\*\* $P<0.0001$  (unpaired  $t$ -test). Error bars represent s.e.m. (B) Quantification of organoid growth in the presence (WENR) or absence (ENR) of Wnt3 in culture medium at days 5 and 8 after isolation of PSI crypts from control or  $\Delta N$  mice ( $n=3$  per group). \* $P<0.05$  (unpaired  $t$ -test). n.s., not significant. Error bars represent s.d. (C) Upper panels: Representative images of crypt organoids cultured in ENR medium (without Wnt) at day 1 (d1) and day 4 (d4) after isolation of PSI crypts from control and  $\Delta N$  mice ( $n=4$  per group). Black arrows indicate viable organoids. Lower panels: Representative images of crypt organoids cultured in WENR medium (plus Wnt) at day 1 (d1) and day 5 (d5) after isolation of PSI crypts from control and  $\Delta N$  mice ( $n=3$  per group). (D) Representative immunofluorescence staining using an anti-lysozyme antibody (green) and DAPI (blue) of control and  $\Delta N$  crypt organoids at d2 or d7 in ENR medium. (E) Representative images of immunofluorescence staining using E-cadherin (E-Cad, red) and Muc2 (green) antibodies on control and  $\Delta N$  crypt organoids at d2 in ENR or WENR medium, or of Alcian Blue staining of *Lgr5-EGFP* (control) and *Lgr5-EGFP*; $\Delta N$  ( $\Delta N$ ) organoids, generated from single *Lgr5*<sup>+</sup> cells isolated by FACS, at d7 grown in WENR medium. Scale bars: 50  $\mu$ m. (F,G) qRT-PCR for the Paneth cell marker lysozyme and the goblet cell marker Muc2 using RNA from organoids at d7 in ENR medium (F) or WENR medium (G). \* $P<0.05$ , \*\*\*\* $P<0.0001$  (multiple  $t$ -test with Bonferroni correction). Error bars represent s.e.m.

*Lgr5* and *Ascl2* was also reduced in  $\Delta N$  organoids grown in ENR medium (Fig. S6C), but addition of Wnt3 caused a significant increase of both markers (Fig. S6D). Thus, the rescued growth of  $\Delta N$  organoids in the presence of Wnt might be due to the re-establishment of a functioning stem cell niche (Fig. 6B,C; Fig. S6A,B).

Similar to observations in SI crypts, NF- $\kappa$ B was predominantly active in Paneth cells of organoids derived from  $\kappa$ -EGFP mice (Fig. S6E), and  $\Delta N$  organoids had strongly reduced numbers of Paneth cells and increased numbers of goblet cells compared with controls (Fig. 6D,E). This was verified by qRT-PCR of the Paneth cell marker lysozyme and the goblet cell marker *Muc2* in  $\Delta N$  and control organoids (Fig. 6F). In contrast to growth restoration of  $\Delta N$  organoids, the presence of Wnt3 in the culture medium did not result in any changes of lysozyme or *Muc2* expression (Fig. 6E,G). These data indicate that in  $\Delta N$  organoids Wnt3 alone is not sufficient to re-establish Paneth cell formation and reduce the numbers of goblet cells.

### Wnt3, Wnt10A and Sox9 expression is dependent on NF- $\kappa$ B activity in SI crypts and organoids

To elucidate the molecular mechanism behind defects in Paneth cell differentiation in  $\Delta N$  mice, we examined Wnt activity and

expression of Wnt pathway components that have previously been linked to NF- $\kappa$ B signaling or IEC self-renewal. A Wnt reporter using the *Axin2* promoter (*cond-lacZ*) and analysis of *Axin2* mRNA expression suggested that overall Wnt activity was maintained in the crypts of  $\Delta N$  mice (Fig. S7A,B). This may be due to TA cells migrating into the crypts in the absence of Paneth cells (Fig. 2A,C; Fig. S7A) (Mori-Akiyama et al., 2007; Durand et al., 2012; Kim et al., 2012). However, expression of *Wnt3* mRNA was significantly reduced in isolated crypts of  $\Delta N$  mice compared with controls (Fig. 7A). *Wnt3* is considered the main Wnt ligand produced in SI crypts (Gregorieff et al., 2005; Farin et al., 2012). Interestingly, mRNA expression of the Wnt ligand *Wnt10a* was also strongly downregulated or absent in SI crypts and crypt organoids (grown in ENR medium) of  $\Delta N$  mice compared with controls, as shown by ISH or via qRT-PCR (Fig. 7B,C). Similar to an earlier study, our ISH results suggest that *Wnt10a* is expressed in Paneth cells (Fig. 7B) (Berger et al., 2016). *Wnt3* has not yet been identified as NF- $\kappa$ B target gene, which is why reduced *Wnt3* mRNA expression might be connected with the lack of Paneth cells in the crypts of  $\Delta N$  mice (see above and Fig. 4). However, *Wnt10a* has been identified as downstream target of NF- $\kappa$ B previously (Krappmann et al., 2004; Zhang et al., 2009; Tomann et al., 2016). These results support our

**Fig. 7. *Wnt3*, *Wnt10a* and *Sox9* expression is significantly reduced or absent in SI crypts and crypt organoids of  $\Delta N$  mice.** (A) qRT-PCR for *Wnt3* using RNA from isolated PSI crypts of  $\Delta N$  and control mice ( $n=3$  per group).  $***P<0.001$  (unpaired Welch's  $t$ -test). Error bars represent s.e.m. (B) Left: ISH using antisense riboprobes for *Wnt10a* on PSI sections of control and  $\Delta N$  mice ( $n=3$  per group). Black arrows point to mRNA expression in crypts. Insets show magnified images of crypts. Right: Sense riboprobe for *Wnt10a* on PSI sections of controls (negative control; top), and *Wnt10a* antisense riboprobe on sagittal skin sections showing *Wnt10a* mRNA expression in the inner root sheath of an anagen hair follicle (black arrows; positive control; bottom). (C) qRT-PCR for *Wnt3*, *Wnt10a* and *Axin2* using RNA from bulk crypt organoids of  $\Delta N$  and control mice ( $n=3$  per group) cultured without Wnt (ENR).  $**P<0.01$ ,  $***P<0.001$  (multiple  $t$ -test with Bonferroni correction). Error bars represent s.e.m. (D) ISH using an antisense riboprobe for *Sox9* on PSI sections of control and  $\Delta N$  mice. Black arrows point to mRNA expression in crypts. Insets show magnified images of crypts. (E) qRT-PCR for *Sox9* using RNA from PSIs of  $\Delta N$  and  $I\kappa B\alpha^{IEC-KO}$  mice ( $n=3$  per group). Expression level of control mice set to one.  $**P<0.01$  (unpaired Welch's  $t$ -test). Error bars represent s.e.m. (F) IHC using a Sox9 antibody on PSI sections of control and  $\Delta N$  mice ( $n=3$  per group) shows strongly reduced Sox9 expression in  $\Delta N$  mice. Insets show magnified images of crypts. Scale bars: 50  $\mu$ m (main panels); 20  $\mu$ m (insets). (G) PSI cytoplasmic and nuclear extracts of control and  $\Delta N$  mice ( $n=3$  per group) were used for SDS-PAGE western blotting to confirm the presence of nuclear Sox9 (arrowhead). Lactate dehydrogenase A (Ldha) was used as positive control for cytoplasmic extracts. Parp1 and active nuclear non-phosphorylated  $\beta$ -catenin were used as positive controls for nuclear extracts.

findings of impaired Wnt signaling in SI crypts when NF- $\kappa$ B activity is suppressed (see above and Fig. S5).

The transcription factor Sox9 (SRY-box containing gene 9) is required for Paneth cell differentiation (Bastide et al., 2007; Mori-Akiyama et al., 2007) and has been described as a Wnt, but also as a direct NF- $\kappa$ B target gene (Blache et al., 2004; Tomann et al., 2016). mRNA and protein expression of Sox9 was significantly diminished or absent in SI crypts of  $\Delta N$  mice compared with controls (set to 1) or with *I $\kappa$ B $\alpha$ <sup>IEC-KO</sup>* mice (Fig. 7D-G; Fig. S7C). Furthermore, we show that Sox9 is co-expressed with EGFP in  $\kappa$ -EGFP reporter mice (Fig. S7D-I). Thus, our data indicate that in Paneth cells and their progenitors Sox9 expression is at least partly regulated by NF- $\kappa$ B, which is why loss of NF- $\kappa$ B activity would result in defective Paneth cell differentiation in secretory progenitors.

## DISCUSSION

Self-renewal of the small intestinal epithelium relies mainly on Lgr5-positive stem cells (CBCs) in the crypts and on gradients of special signals, in particular Wnt and Notch (reviewed by Barker et al., 2008; Clevers, 2013; Gehart and Clevers, 2019). Local concentrations of Wnt and Notch determine the type of secretory cell to be formed or whether an enterocyte is generated. Thus far, it has remained unknown whether NF- $\kappa$ B signaling also plays a role in proper SI self-renewal or lineage specification. Ubiquitous suppression of NF- $\kappa$ B ( $\Delta N$ ) did not result in intestinal inflammation concomitant with alterations in IEC proliferation and increased apoptosis, which was observed in IEC-specific IKK/NF- $\kappa$ B KO (Schwitalla et al., 2013; Vlantis et al., 2016); reviewed by Taniguchi and Karin, 2018). This enabled us to demonstrate for the first time an essential role for NF- $\kappa$ B in Paneth versus goblet cell fate decisions. As this was confirmed in organoids, which are devoid of mesenchymal tissue, we conclude that this is an IEC-intrinsic NF- $\kappa$ B function. Paneth cells are the main producers of Wnt and Notch ligands, which are necessary for crypt homeostasis and *ex vivo* organoid growth (Sato et al., 2009, 2011). *In vivo* absence of Paneth cells is thought to be overcome by Wnt production in the underlying mesenchyme, for instance by subepithelial telocytes (Durand et al., 2012; Farin et al., 2012; Kim et al., 2012; Shoshkes-Carmel et al., 2018), which is why the overall growth of the SI epithelium appeared to be normal in  $\Delta N$  mice (see Fig. 2).

The crypts of  $\Delta N$  mice were mainly filled with highly proliferative TA cells that are derived from Lgr5-positive CBCs and are normally located adjacent to SI crypts. This is expected because it was previously observed in the absence of Paneth cells in *Atoh1* (*Math1*) and *Sox9* KO mice (Mori-Akiyama et al., 2007; Durand et al., 2012; Kim et al., 2012). TA cells comprise progenitors for absorptive and secretory cell lineages (reviewed by Tetteh et al., 2015). Our TEM images showed that, in addition to TA cells,  $\Delta N$ -positive crypts contained aberrant immature intermediate cells, and together these cell types, which are normally not present in crypts, might have resulted in no change to proliferation rates or expression of *Prom1*, *Msi1* and *Ephb3* (Figs 2 and 5; Fig. S5). The significantly reduced Wnt-dependent expression of *Lgr5*, *Ascl2*, *Tnfrsf19* or *Edn1* observed in SI crypts of  $\Delta N$  mice may thus have been caused by decreased Wnt activity together with changes in CBC numbers and/or their differentiation rate.  $\Delta N$  organoids grown in Wnt3-containing culture medium re-express *Lgr5* and *Ascl2* at higher levels than controls, suggesting that Wnt rather than NF- $\kappa$ B is the major regulator of Lgr5 and Ascl2. It also indicates that NF- $\kappa$ B activity is essential for fine-tuning of Wnt signaling in SI crypts. Various studies on inflammation or

tumorigenesis in the intestinal epithelium have suggested that local aberrant NF- $\kappa$ B activation enhances Wnt signaling and CBC niche expansion, whereas deletion of NF- $\kappa$ B p65/RelA in IECs led to a delay of this expansion (Schwitalla et al., 2013; Mikuda et al., 2020; Zhao et al., 2020). However, it currently remains unknown whether NF- $\kappa$ B has a direct role in CBC homeostasis. The occasional NF- $\kappa$ B activity observed in what appeared to be CBCs (see Fig. 1) might also correspond to already-primed stem cells about to migrate out of the crypt to become secretory progenitors.

Paneth and goblet cells derive from the same secretory progenitor. Paneth cells are formed in an environment of high Wnt/ $\beta$ -catenin, whereas goblet cell formation requires low Wnt activity (for a review, see Buske et al., 2011). The exact mechanism of this switch remains unknown, but fine-tuning of Wnt signaling might in part be regulated by Shp2/Mek1/MAPK signaling that interferes with Tcf4/ $\beta$ -catenin signaling in goblet/Paneth cell progenitors (Heuberger et al., 2014). According to this study, goblet cell differentiation requires high Shp2/MAPK activity, which inhibits Wnt/ $\beta$ -catenin signaling, whereas Paneth cells are only formed in an environment of low Shp2/MAPK and, hence, high Wnt/ $\beta$ -catenin activity (Heuberger et al., 2014). Increased numbers of goblet cells at the expense of Paneth cells indicate that fine-tuning of Wnt activity is disturbed in  $\Delta N$  mice, in which one would expect high Shp2/MAPK signaling and low Wnt activity. In line with this, expression of *Wnt3* and *Wnt10* mRNA was significantly reduced in SI crypts and in organoids derived from crypts or a single Lgr5-positive CBC. A potential connection between Shp2/MAPK signaling and NF- $\kappa$ B activity in SI crypt homeostasis remains to be evaluated. Although Wnt3 is required for stem cell niche maintenance, the role of Wnt10a is not well defined yet. It was shown previously that Wnt10a is expressed in mature Paneth cells (Berger et al., 2016), suggesting that it might regulate CBC proliferation and maintenance together with Wnt3, but it may additionally control Paneth cell differentiation in the secretory progenitor. We have demonstrated that Wnt3 alone is not sufficient to rescue loss of Paneth cells in  $\Delta N$  organoids, which strongly suggests that NF- $\kappa$ B regulates the expression of additional Wnts required for proper Paneth cell differentiation and maturation. Thus, Paneth cells may direct their own generation. Interestingly, in skin appendages, such as hair follicles or filiform papillae of the tongue, Wnt10a is specifically required for differentiation and morphogenesis in post-mitotic cells that have already been primed (Hammerschmidt and Schlake, 2007; Xu et al., 2017; Krieger et al., 2018).

Loss of Sox9 expression and the consequential lack of Paneth cell differentiation alone does not lead to increased numbers of goblet cells (Bastide et al., 2007; Mori-Akiyama et al., 2007), as observed in  $\Delta N$  mice. Thus, the increased numbers of goblet cells in  $\Delta N$  mice must be due to molecular and/or physiological changes in addition to ablation of Sox9 expression due to suppressed NF- $\kappa$ B activity in secretory progenitors. We observed decreased Dll1 expression in crypts and organoids of  $\Delta N$  mice, which inevitably will lead to reduced local Notch signaling. Notch ligands Dll1 and Dll4 are both expressed on mature Paneth cells, are partly redundant, activate Notch signaling via Notch receptors on adjacent CBCs and are required for stem cell maintenance (Pellegrinet et al., 2011; Sato et al., 2011). However, Dll1 is also highly expressed on secretory progenitors and its expression appears to be associated with proliferation cessation (Stamatakis et al., 2011; van Es et al., 2012; for a review, see Tetteh et al., 2015). Furthermore, *Dll1* KO mice have increased goblet cell numbers (Pellegrinet et al., 2011; Stamatakis et al., 2011). Thus far, *Dll1* has not been identified as a target gene

of NF- $\kappa$ B. It therefore may be linked to loss of Paneth cells and/or to an as-yet-unknown effect in secretory progenitors due to suppressed NF- $\kappa$ B activity. Taken together, in  $\Delta N$  mice decreased *Dll1* expression in SI crypts, together with local loss of *Wnt3*, *Wnt10a* and *Sox9* expression, might tilt the fate decisions of secretory progenitors towards goblet cells.

The upstream activator of NF- $\kappa$ B that specifically regulates Paneth cell differentiation in the SI epithelium has not yet been defined. Particular members of the TNF family appear to activate NF- $\kappa$ B in physiological processes unrelated to inflammation or development of the immune system. In fetal skin appendage development and hair follicle self-renewal, NF- $\kappa$ B is exclusively activated by the TNF family member *Eda-A1* (ectodysplasin A1; also known as *Eda*; Kumar et al., 2001; Schmidt-Ullrich et al., 2001; Laurikkala et al., 2002; Schmidt-Ullrich et al., 2006; Krieger et al., 2018). *Eda-A1* signaling does not seem to be responsible for activation of intestinal NF- $\kappa$ B activity, because the SIs of *Eda-A1* mutant mice (*tabby* mice) were indistinguishable from controls (K.K. and R.S.-U., unpublished data). The search for activators of NF- $\kappa$ B signaling in the SI will thus continue in the future, but *Tnfrsf19* is a potential candidate as it is expressed in SI crypts, is regulated by Wnt in *Lgr5*-positive CBCs and appears to modulate Wnt signaling in human colon carcinoma cell lines (Faflek et al., 2013). Note that decreased Wnt ligand expression in SI crypts of  $\Delta N$  mice might also have led to reduced *Tnfrsf19* expression (see Fig. S5E). A recent publication also showed that the *Lgr5-Tnfrsf19* interaction is able to activate NF- $\kappa$ B in colon carcinoma cell lines (Lai et al., 2020). Importantly, the current study is yet another proof that signaling crosstalk between NF- $\kappa$ B and Wnt plays a role not only in tumorigenesis (Schwitalla et al., 2013), but also in physiological processes. A reciprocal requirement of NF- $\kappa$ B and Wnt signaling is essential for fetal hair follicle induction to prevent premature differentiation, but also for subsequent morphogenesis and in adult hair follicle cycling (Fliniaux et al., 2008; Zhang et al., 2009; Klopper et al., 2014; Tomann et al., 2016; Krieger et al., 2018). In hair follicles, this mainly involves *Wnt10a* and *Wnt10b*, which are target genes of NF- $\kappa$ B, whereas Wnt upregulates *Edar* (ectodysplasin-A receptor) expression, the receptor for *Eda-A1* (Zhang et al., 2009). Although *Wnt10b* is not expressed in IECs (data not shown), our data confirm previous findings of *Wnt10a* expression in SI crypts (Berger et al., 2016). It will thus be important to examine a role for NF- $\kappa$ B–*Wnt10a* interactions in SI crypt homeostasis in the future.

## MATERIALS AND METHODS

### Mice

All aspects of animal care and experimental protocols were approved by the Berlin Animal Review Board (LAGeSo Berlin; Reg. G 0077/08, G 0082/13, G 0358/13 and X 9013/11) and all animal studies were performed in accordance with ARRIVE guidelines. Mice were genotyped by PCR of genomic DNA. The following genetically modified lines were used for our study: *B6-Tg( $\kappa$ -Gal)3Rsu ( $\kappa$ -Gal)* (Schmidt-Ullrich et al., 1996; Schmidt-Ullrich et al., 2001), *B6-Tg( $\kappa$ -EGFP)3Pt/Rsu ( $\kappa$ -EGFP)* (Tomann et al., 2016), *129;129P2-ctnnb1<sup>tm(NFKBIA $\Delta$ N)/1RSU( $\Delta$ N)</sup>* (Schmidt-Ullrich et al., 2001), *129;129P2-ctnnb1<sup>tm(NFKBIA $\Delta$ N)/1RSU(loxP- $\Delta$ N)</sup>* (Schmidt-Ullrich et al., 2001; Freund et al., 2005; Henke et al., 2007; Krieger et al., 2018), *Tg(Vil-cre)20Syr (villin-Cre)* (el Marjou et al., 2004), *B6;129P2-Nfkb1a<sup>tm1Kbp</sup>* (Beg et al., 1995; Rupec et al., 2005), *B6;129P2-Nfkb1a<sup>tm1Kbp</sup>;Tg(Vil-cre)20Syr (I $\kappa$ B $\alpha$ <sup>IEC-KO</sup>)* (Mikuda et al., 2020), *B6.129P2-Lgr5<sup>tm1(cre)/ERT2</sup>Cle (Lgr5-EGFP-IRES-creERT2)*, here referred to as *Lgr5-EGFP* (Barker et al., 2007), *B6-Axin2<sup>tm1Mdc6</sup> (cond-lacZ)* (Lustig et al., 2002; Yu et al., 2005), *Spdef<sup>tm1.1Cle</sup>* (Gregorieff et al., 2009).

For each experiment three to seven mice per group (line) were used. Mice were sacrificed at 8–12 weeks of age, or P9 and P15 as indicated.

### Organoid cultures

Mouse intestine organoid culture in Matrigel was performed as described previously (Sato and Clevers, 2013). Briefly, duodenal (PSI) crypts were isolated by filtration (70  $\mu$ m) and centrifugation (300 *g* for 5 min) of selected fractions following mechanical dissociation (shaking) of villi and crypts, a 5 min incubation at room temperature with 8 mM EDTA and a 25 min rotation at 4°C with 2 mM EDTA. Approximately five-hundred crypts were embedded in 50  $\mu$ l Matrigel (BD Biosciences, 356,231) and cultured in Advanced DMEM/F12 medium (12634; Life Technologies), supplemented with N2 and B27 (Life Technologies, 17502-040 and 17504-044, respectively), mNoggin (PeproTech, final concentration 100 ng/ml), R-spondin (R&D Systems, final concentration 500 ng/ml), mEGF (mouse epidermal growth factor, 315-09, PeproTech; final concentration 50 ng/ml) and N-acetylcysteine (5619, Tocris Bioscience; final concentration 500  $\mu$ M). For single-cell sorting experiments, isolated crypts were incubated in culture medium for 45 min at 37°C followed by trituration with a glass pipette. Dissociated cells were passed through a cell strainer with a pore size of 40  $\mu$ m. EGFP-positive cells were sorted by flow cytometry (BD FACS ARIA II). Single viable epithelial cells were gated by forward scatter, side scatter and pulse-width parameter, and by negative staining for propidium iodide. Sorted cells were collected in culture medium and embedded in Matrigel containing Jagged-1 peptide (1  $\mu$ M; AnaSpec) at 100 cells/well (in 48-well plates, 10  $\mu$ l Matrigel). After sorting the culture medium (250  $\mu$ l for 48-well plates) was supplemented with Y-27632 (10  $\mu$ M; Sigma-Aldrich) for 24 h. Thereafter, Y-27632-free medium was used and changed every day. For passage, organoids were removed from Matrigel and mechanically dissociated into single-crypt domains, and then transferred to new Matrigel.

### Immunofluorescence, immunohistochemistry, ISH, TUNEL assay, BrdU and EdU incorporation

Unless indicated otherwise, histological and biochemical analyses were performed on sections of the duodenum (PSI) of 8- to 12-week-old mice. Cleansed intestinal pieces were coiled prior to treatment ('swiss role'; Moolenaar and Ruitenberg, 1981). For ISH, immunohistochemistry (IHC) or immunofluorescence, the tissue was fixed in Bouin's fixative (for ISH) or in 4% paraformaldehyde/MEM overnight at 4°C, followed by dehydration and paraffin-embedding. Immunofluorescence and ISH on paraffin sections were performed as described previously (Gregorieff et al., 2005; Zhang et al., 2009; Heuberger et al., 2014). For IHC, a 3,3'-diaminobenzidine (DAB) kit (882014 2-Solution DAB Kit, Invitrogen) was used for antibody detection. Alcian Blue, Hematoxylin & Eosin, or nuclear DAPI (blue) or Fast Red staining were carried out according to standard protocols. TUNEL staining was performed on 5- $\mu$ m-thick sections of PSIs using the In Situ Cell Death Detection kit (11684795910, Roche) according to the manufacturer's protocol. For proliferation studies, BrdU in 0.9% NaCl was injected intraperitoneally (100  $\mu$ g/g body weight). PSI samples were taken after 4 or 24 h, dehydrated and embedded in paraffin. Visualization was performed using the M.O.M. Immunodetection Kit (PK-2200, Vector Laboratories). EdU incorporation and detection was performed using the Click-iT EdU Cell Proliferation Kit for Imaging and Alexa Fluor 555 dye (C10338, Invitrogen) as described in the manufacturer's protocol.

Images were collected using a ZEISS LSM800 or Leica SP5-7-8 and processed using ImageJ.

Antibodies and ISH cDNA probes are provided in supplementary Materials and Methods. Images were obtained using a conventional (Leica SP5-7-8) or confocal (Zeiss LSM800) Zeiss microscope.

X-Gal staining for detection of  $\beta$ -galactosidase activity was as described previously (Schmidt-Ullrich et al., 1996, 2001). Tissue was stained as whole-mount, dehydrated in an ethanol series (30–100%) and embedded in Technovit 7100 plastic (Heraeus Kulzer). Sections of 5–8  $\mu$ m thickness were counterstained with 0.1% Pyronin G (45005, Sigma-Aldrich).

PTAB staining was performed on 5- $\mu$ m-thick sections for scoring of PT+AB<sup>-</sup> (Paneth cells), PT+AB<sup>+</sup> (goblet cells) and PT+AB<sup>+</sup> (intermediate cells) cell numbers, as described previously (Dekaney et al., 2019).

## TEM

Dissected pieces of PSI tissue of 2-3 mm<sup>3</sup> from 8- to 12-week-old mice were fixed by immersion in 4% (w/v) paraformaldehyde and 2.5% (v/v) glutaraldehyde in 0.1 M phosphate buffer for 2 h at room temperature. Samples were post-fixed with 1% (v/v) osmium tetroxide for 3 h at room temperature, dehydrated in a graded series of ethanol, and embedded in PolyBed 812 resin (Polysciences). Ultrathin sections (60-80 nm) were stained with uranyl acetate and lead citrate, and examined at 80 kV with a Zeiss EM 910 electron microscope. Images were acquired with a Quemesa CCD camera using iTEM software (EMSIS).

## Quantification of Paneth cells and goblet cells

Lysozyme protein specifically expressed in secretory granules of Paneth cells was used as a surrogate marker to identify Paneth cells in the SI. Paraffin sections (5  $\mu$ m) were stained with an anti-lysozyme antibody and a conventional microscope was used to take pictures at 100 $\times$  magnification of random, non-overlapping SI areas within a section. The cell-counting plugin of ImageJ was used to count lysozyme-positive and -negative crypts, and the percentage of lysozyme-positive crypts out of total number of crypts was calculated. A minimum of 150 crypts was counted for three to five biological replicates [ $\Delta N$  (suppressed NF- $\kappa$ B activity) and control mice]. For quantification of goblet cells, PSI (proximal small intestine, duodenum) sections were stained with Alcian Blue. Conventional microscope analysis was performed at 600 $\times$  magnification by counting Alcian Blue-positive cells per crypt for 50 crypts for three biological replicates ( $\Delta N$ , *villin*- $\Delta N$  and control mice). Unpaired Student's *t*-test with Welch's correction was used to calculate *P*-values. *P*  $\leq$  0.05 was considered significant.

## Quantitative RT-PCR

For quantitative real-time PCR (qRT-PCR), cDNA was generated from total RNA using the iScript cDNA Synthesis Kit (Bio-Rad Laboratories). Primers are provided in supplementary Materials and Methods. Data analysis was performed with CFX96 software (Bio-Rad Laboratories), which is based on the  $\Delta\Delta$ CT method. All target genes were standardized to reference genes *Gapdh* and *Hprt* (*M*-value  $<$  0.5 for homogeneous samples). Outliers were defined by the Grubbs test using GraphPad Prism 8. All qRT-PCR results were treated according to MIQE guidelines (Bustin et al., 2009). All control values were normalized to one.

## Protein extractions and western blotting

A freshly isolated piece of small intestine was shock-frozen in liquid nitrogen, pulverized using a mortar and incubated in 500  $\mu$ l RIPA buffer for 4 h on a rotating table. The sample was centrifuged for 30 min at 14,000 rpm (21,952 g). Cytoplasmic and nuclear extracts were performed after crypt isolation from the small intestine. The supernatant was used for western blotting in SDS-PAGE and protein concentration determined using the Bradford method as reported elsewhere (Mikuda et al., 2018).

## Statistical analyses

Statistical analyses were performed using GraphPad Prism 8. Unless stated otherwise, significance was estimated using either unpaired Student's *t*-test with Welch's correction or multiple *t*-test with Bonferroni correction and two-way ANOVA. *P*-values less than 0.05 were defined as significant. Mean and s.e.m. are reported in the figure legends. FACS data were analyzed using FlowJo\_v10, and ImageJ was used for protein and QuPath for cell quantification.

## Acknowledgements

We thank Doris Lange, Lisa Spatt and Janine Wolff (R.S.-U.), as well as Jasmin Gerkrath and Gudrun Kliem (C.K.) for excellent technical help; Dr Hans-Peter Rahn (Flow Cytometry, MDC) for assistance in FACS; Gregory Shackleford for the *Wnt10a* probe; Daniel Louvard and Silvie Robine for providing *villin-Cre*; Nick Barker and Hans Clevers for providing *Lgr5-EGFP-IRES-creERT2* mice; Alex Gregorieff, Hans

Clevers and Jeffrey A. Whitsett for providing *Spdef*<sup>-/-</sup> mice; Walter Birchmeier for providing *cond-lacZ* mice; and Anton Aebischer for critical reading of the manuscript.

## SUPPLEMENTARY METHODS

### In situ hybridization probes

In situ hybridization was carried out using the following mouse cDNA probe templates: *Axin2* (nt 282 – 918 of *Axin2* cDNA; BC057338) kindly provided by J. Huelsken, ISREC, Lausanne, Switzerland/W. Birchmeier, MDC, Berlin, Germany. *Cryptidin-1* (nt 3 – 401 of NM\_010031/AA871421.1; I.M.A.G.E. ID 1096215), kindly provided by M. van de Wetering/H. Clevers, Hubrecht Institute, Utrecht Netherlands. Murine *Nfkb1a* ( $\text{IkB}\alpha$ ; nt 1 – 1091; U36277/NM010907). *Olfm4* (NM\_001030294), kindly provided by J. Heuberger/W. Birchmeier, MDC, Berlin, Germany. pBSK-*Sox9* (first 1800bp of *Sox9* cDNA), kindly provided by T. Willnow, MDC, Berlin, Germany. NM\_011448). *Wnt10a* (nt 1295 - 2487, U61969), kindly provided by G. Shackleford, UCLA, USA).

### Antibodies

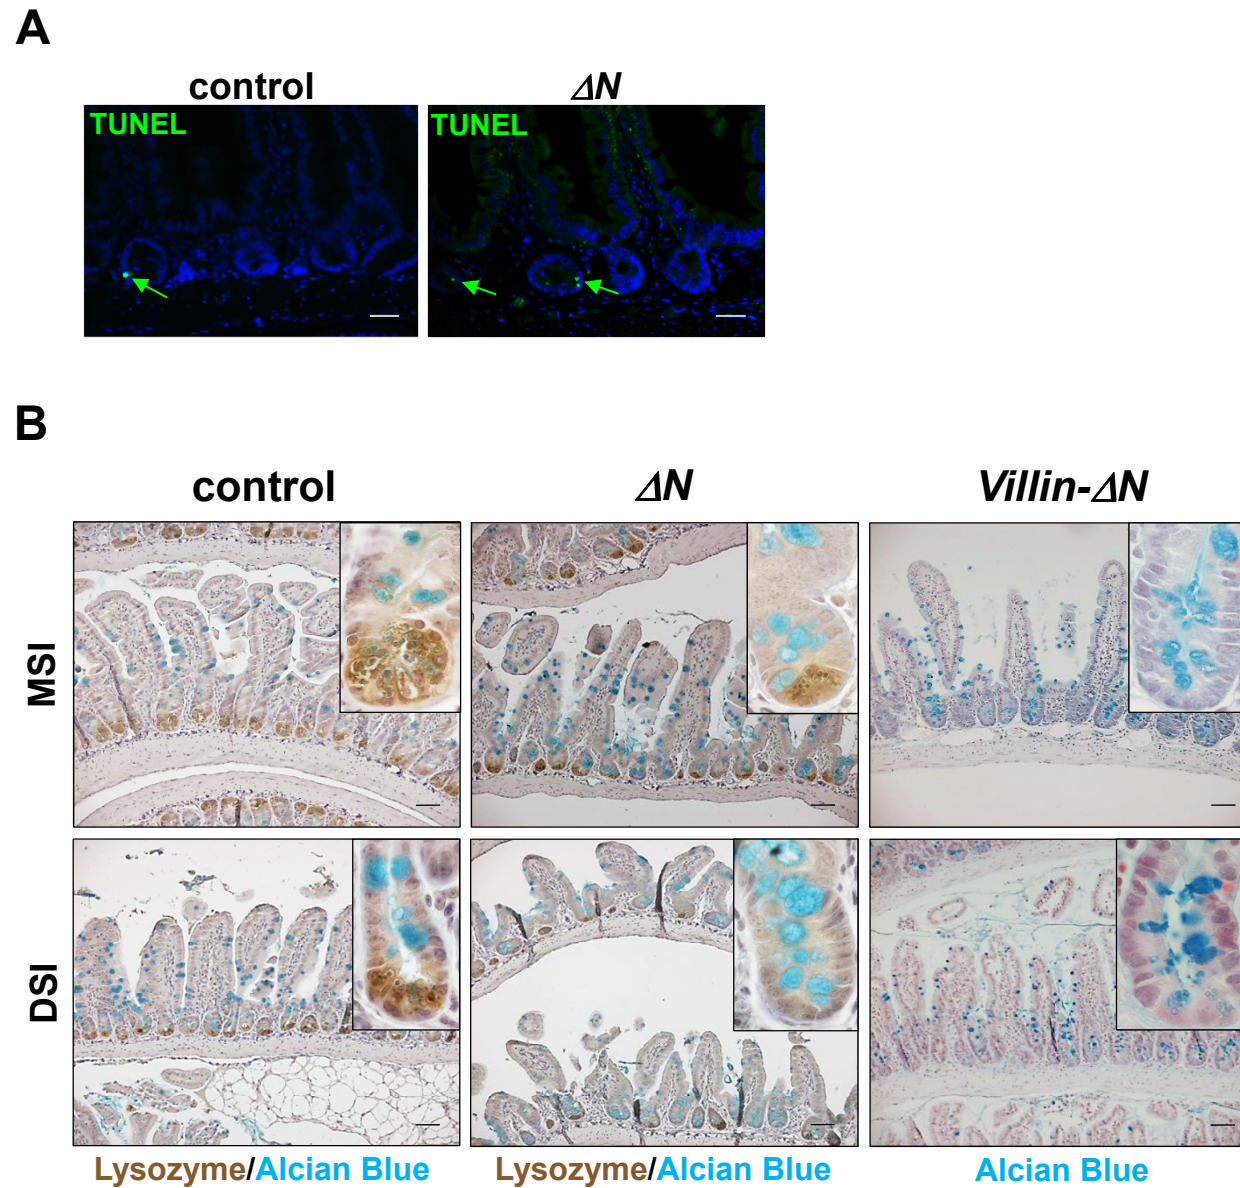

- Non-phospho (active)  $\beta$ -Catenin (Ser33/37/Thr41), rabbit, Cell Signaling (#8814), 1:500
- BrdU, mouse, Sigma (BU33), 1:500
- Chromogranin A, rabbit, Abcam (15160), 1:300
- Cleaved Caspase-3 (Asp175), rabbit, Cell Signaling (9664), 1:400
- Digoxigenin-AP Fab fragments, sheep, Roche (11093274910), 1:1000
- E-Cadherin, mouse, BD (610181), 1:500
- EGFP, chicken, Abcam (ab13970), 1:400
- Ki67, rabbit, Abcam (ab15580), 1:100

- Ldha (Lactate dehydrogenase A), Santa Cruz (sc-27230), 1:1000
- Lysozyme, rabbit, DAKO (A 0099), 1:1000
- Mmp7 (matrix metalloproteinase-7), Santa Cruz sc-515703, 1:1000
- Muc2 (Mucin 2), rabbit, Santa Cruz (sc-15334), 1:100
- Olfm4, rabbit, Cell signaling (D6Y5A), 1:400
- Parp1 (Poly(ADP-ribose)-polymerase 1), mouse, Santa Cruz (sc-8007), 1:1000
- Sox9 (SRY-box 9), rabbit, Santa Cruz (sc-20095) 1:100, (Vidal et al. 2005; Nowak et al. 2008), and rabbit, Millipore (AB5535), 1:200.

**Fig. S1. (A) NF- $\kappa$ B activity is suppressed in SI crypts of  $\Delta N$  mice.** *In situ* hybridization on PSI sections of control and  $\Delta N$  mice using a riboprobe for mouse *Nfkb1a* (NF- $\kappa$ B inhibitor I $\kappa$ B $\alpha$ , bona fide target gene of NF- $\kappa$ B). Arrowheads point to *Nfkb1a* mRNA expression. Scale bars = 50 $\mu$ m. Note that in  $\Delta N$  mice a C-terminal deletion mutant of the human I $\kappa$ B $\alpha$  was used which is not detected by the murine *Nfkb1a* riboprobe (see (Schmidt-Ullrich et al. 2001; Schmidt-Ullrich et al. 2006)). **(B – C)  $\beta$ -catenin protein expression is maintained in  $\Delta N$  and *loxP- $\Delta N$*  mice.** **(B)** PSI whole cell protein extracts of control,  $\Delta N$  and *loxP- $\Delta N$*  mice (n=3/group n1 or n2) were used for SDS-PAGE Western blotting with an antibody against nuclear  $\beta$ -catenin.  $\beta$ -actin was used as loading control. **(C)** Quantification of nuclear  $\beta$ -catenin protein expression normalized to  $\beta$ -actin (from **(B)**). n.s.= not significant,  $p=0.658$  (one-way Anova), error bars = SEM. Note that  $\Delta N$  and *loxP- $\Delta N$*  mice maintain levels of nuclear  $\beta$ -catenin protein expression that are identical to controls, in spite of one-allelic expression from *Ctnnb1* gene (see (Schmidt-Ullrich et al. 2001)). **(D - E) No increase in inflammatory cytokines in small intestines of  $\Delta N$  mice.** **(D)** Quantitative real-time PCR (qRT-PCR) for inflammatory cytokines (*Cxcl12*, *Icam*, *Il6*, *Tnfa*, and *Il1a*) using RNA from PSIs of  $\Delta N$  and control mice (n=3/group). Observed differences were statistically insignificant. Error bars = SEM. **(E)** qRT-PCR for inflammatory cytokines (*Il6*, *Il1a*, *Tnfa*, *Icam1*, *Cxcl12*) using RNA from bulk organoids from *I $\kappa$ B $\alpha$ <sup>JEC-KO</sup>* mice (n=4; constitutively increased NF- $\kappa$ B activity in the SI epithelium; used as positive control for **(D)**). mRNA expression was normalized to 2 reference genes, *Hprt1* and *Sdha* (Succinate dehydrogenase complex, subunit A). Expression of control animals (n=4) was normalized to 1. Mean ratio of *I $\kappa$ B $\alpha$ <sup>JEC-KO</sup>* to control is shown. \*\*:  $p<0.01$ , error bars = SEM. **(F)** Quantitative real-time PCR (qRT-PCR) for NF- $\kappa$ B target genes that are known to be upregulated in inflammatory bowel disease (IBD; see (Mikuda et al. 2020)). Left panel: *Nos2* (Nitric Oxide Synthase), *Nox1* (NADPH Oxidase 1), *Tnfaip3* (A20; Tumor Necrosis Factor alpha-induced protein 3), *Lbp* (Lipopolysaccharide Binding Protein). Right panel: *Lcn2* (NGAL, Lipocalin 2). RNA from PSIs of  $\Delta N$ , *I $\kappa$ B $\alpha$ <sup>JEC-KO</sup>* and control mice (n=3/group) was used. Expression of control animals was normalized to 1. \*\*\*:  $p<0.001$ , \*\*\*\*:  $p<0.0001$ , error bars = SEM.

**Fig. S2. (A) No increased apoptosis in SI epithelium of  $\Delta N$  mice.** IF TUNEL staining on PSI sections of  $\Delta N$  mice and controls (n=4/group). Green arrows point to TUNEL-positive cells. Nuclear counterstaining: DAPI. Scale bars = 50  $\mu$ m. **(B) Increased numbers of Alcian blue-positive (goblet) cells also in the jejunum and ileum of  $\Delta N$  mice.** Sections of middle (MSI, jejunum) and distal (DSI, ileum) SI of control,  $\Delta N$  and *Villin- $\Delta N$*  mice (n=3/group) stained either with Alcian Blue (blue) alone or together with an anti-Lysozyme antibody (brown; DAB). Scale bars = 50 $\mu$ m.

**Fig. S3. Reduced numbers of Paneth cells also in the jejunum and ileum of  $\Delta N$  mice.** (A) Anti-Lysozyme antibody staining (green) on sections of middle (MSI, jejunum) and distal (DSI, ileum) SI of control,  $\Delta N$  and *Villin- $\Delta N$*  mice (n=3/group). White arrows indicate remaining Paneth cells in  $\Delta N$  and *Villin- $\Delta N$*  crypts. Scale bars = 50 $\mu$ m. (B – D) **Paneth cell loss in  $\Delta N$  mice was further verified by strongly reduced Cryptdin-1 and MMP7 expression.** (B) In situ hybridization using a riboprobe for *Cryptdin-1* on PSI sections of control,  $\Delta N$  and *Villin- $\Delta N$*  mice (n=3/group). Black arrows indicate remaining Paneth cells in PSI crypts of  $\Delta N$  and *Villin- $\Delta N$*  mice. Due to one Paneth cell/crypt at most, Cryptdin-1 expression is strongly reduced in  $\Delta N$  and *Villin- $\Delta N$*  crypts when compared to controls (see insets). Scale bars = 50 $\mu$ m. (C) Anti-Mmp7 antibody staining on PSI sections of control and  $\Delta N$  mice (n=3/group). White arrows indicate remaining Paneth cells in  $\Delta N$  mice which express Mmp7. Original magnification 200x. (D) Comparing protein expression of Mmp7 in  $\Delta N$  and control mice (n=3/group). PSI whole cell extracts of control and  $\Delta N$  mice were used for SDS-PAGE Western blotting.

**Fig. S4. (A) NF- $\kappa$ B remains active in the absence of goblet and Paneth cell maturation factor Spdef1.**

(A) IHC using anti-EGFP antibody on PSI sections of *Spdef*<sup>-/-</sup>;  $\kappa$ -EGFP (*Spdef* KO) and *Spdef*<sup>+/+</sup>;  $\kappa$ -EGFP (controls) mice (n=3/group). Scale bars = 50 $\mu$ m and 10 $\mu$ m (right panels). White asterisk indicates background staining. (B – D) NF- $\kappa$ B activity is required for postnatal Paneth cell differentiation. (B) Anti-EGFP (red) and -Lysozyme (green) antibody staining on PSI sections of  $\kappa$ -EGFP mice at P9, P15 and 8 weeks of age (n=3/group). Nuclear counterstain: DAPI (blue). NF- $\kappa$ B activity is already detected in Paneth cell precursors at P9. Yellow arrows point to Paneth cells with active NF- $\kappa$ B (P9 and P15). Scale bars upper panels = 50 $\mu$ m, lower panels = 20 $\mu$ m. (C) IHC on PSI sections of control and  $\Delta N$  mice (n=3/group) stained with Alcian Blue and with anti-Lysozyme antibody (brown; DAB). While in controls the number of Paneth cells/crypt increases between P15 and 8 weeks of age, this is not the case in  $\Delta N$  mice. Scale bars = 20 $\mu$ m. (D) Transmission electron microscopy of PSI crypts of  $\Delta N$  and control mice: Quantification of crypts containing Paneth cells in  $\Delta N$  mice compared to controls (n=4/group) confirms data shown in Fig. 2. \*\*\*\*:  $p < 0.0001$ , error bars = SEM.

**Fig. S5. (A, B) Unaltered numbers of enteroendocrine cells in  $\Delta N$  mice.** (A) IHC using an anti-Chromogranin-A antibody on PSI sections of control and  $\Delta N$  mice (n=3/group). Arrows point to enteroendocrine cells. Scale bars = 50 $\mu$ m. (B) qRT-PCR for enteroendocrine markers *Chromogranin-A* (*ChromoA*) and *Somatostatin* (*SST*) using RNA isolated from PSIs of  $\Delta N$  and control mice (n=3/group). Error bars = SEM. (C – H) **Altered expression of Wnt-dependent ISC markers in  $\Delta N$  mice.** (C) In situ hybridization for ISC marker *Olfm4* on PSI (proximal small intestine; duodenum) sections of  $\Delta N$  and control mice (n=3/group). (D, E) qRT-PCR for Wnt-independent (D) and -dependent (E) ISC markers (see (Mikuda et al. 2020)), using RNA from PSIs of control and  $\Delta N$  mice (n=3/group). *Lgr1*: Leucine-rich repeat-containing G-protein coupled receptor 1; *Smoc2*: SPARC-related modular calcium-binding protein 2; *Tert*: Telomerase reverse transcriptase; *Hopx*: Homeodomain-only protein homeobox; *Olfm4*: Olfactomedin 4; *Ccnd1*: Cyclin D1; *Edn1*: Endothelin 1; *Ephb3*: Ephrin type-B receptor 3; *Msi1*: Musashi RNA-binding protein 1; *Prom1*: Prominin 1; *Tnfrsf19*: Troy, TNF receptor superfamily member 19; *Lgr5*: Leucine-rich repeat-containing G-protein coupled receptor 5; *Ascl2*: Achaete scute-like 2; n.s. = not significant, \*:  $p < 0.05$ , \*\*:  $p < 0.01$ ; error bars = SEM. (F) IF using an anti-EGFP (green) antibody on PSI sections of *Lgr5-EGFP* and *Lgr5-EGFP;  $\Delta N$*  mice (n=3/group). Nuclear counterstain: DAPI (blue). Green arrowheads point to scarce *Lgr5* expression in crypts of  $\Delta N$  mice. Scale bar = 100 $\mu$ m. (G) Quantification (in %) of EGFP-positive (*Lgr5*-expressing) cells in  $\Delta N$  compared to control mice (n=5/group) by FACS. \*:  $p < 0.05$ ; error bars = SEM. (H) Quantification (in %) of Ki67- versus *Lgr5*-positive cells in PSI of *Lgr5-EGFP* and *Lgr5-EGFP;  $\Delta N$*  mice (n=3/group). \*:  $p < 0.05$ ; error bars = SEM.

**Fig. S6. Wnt rescues organoid growth in  $\Delta N$  mice.** (A) Single, EGFP-positive cells isolated from *Lgr5-EGFP* (control) or *Lgr5-EGFP; $\Delta N$*  mice ( $\Delta N$ ) by FACS and cultured in presence (WENR) or absence of Wnt (ENR). n=3 independent experiments; d0 – d6 = days of culture. (B) EdU incorporation together with anti-Lysozyme or anti-Muc2 (both green) staining in control and  $\Delta N$  organoids (from 3 mice/group) at culture day 7 (d7) in WENR medium, verified by EdU antibody staining (purple). Nuclear counterstain: DAPI (blue). (C, D) Representative qRT-PCR for stem cell markers *Lgr5* and *Ascl2* using RNA isolated from bulk organoids grown either in ENR or WENR medium. \*\*:  $p < 0.01$ , \*\*\*\*:  $p < 0.0001$ ; error bars = SEM. (E) Representative image of NF- $\kappa$ B activity in Paneth cells of crypt organoids: Anti-EGFP and -Lysozyme antibody staining on cultured organoids obtained from  *$\kappa$ -EGFP* mice (n=3). Yellow arrowheads point to Paneth cells. Scale bar = 20  $\mu$ m. (F) Quantification (in %) of Ki67-positive cells of bulk control and  $\Delta N$  organoids grown either in ENR or WENR medium. Two-way ANOVA with Bonferroni's multiple comparison test, \*\*\*\* $p < 0.0001$ , n.s. = not significant; error bars = SEM.

**Fig. S7. (A, B) Overall Wnt/ $\beta$ -Catenin activity appears to be maintained in crypts of  $\Delta N$  mice**

**(A) Cryosections**

of whole mount X-Gal-stained (blue) PSIs obtained from WNT reporter *cond-lacZ* (controls) and *cond-lacZ; $\Delta N$*  mice (n=3/group). Black arrows point to  $\beta$ -galactosidase expression (= Wnt activity) in transit amplifying (TA) cells in controls (upper panels) and in the bottom of  $\Delta N$ -positive crypts (lower panels). Red arrow points to CBC stem cells. Scale bars = 30 $\mu$ m. **(B) Left panels:** In situ hybridization for canonical Wnt/ $\beta$ -Catenin target gene *Axin2* on PSI sections of control and  $\Delta N$  mice (n=3/group). Insets: Asterisks in controls indicate Paneth cells. Black arrows point to *Axin2* in TA cells of controls and to aberrant *Axin2* mRNA expression in  $\Delta N$ -positive crypt bottoms. Scale bars = 50 $\mu$ m. Right panel: qRT-PCR for *Axin2* using RNA from PSIs of  $\Delta N$  and control mice (n=3/group), normalized to 1 (control). n.s., not significant. **(C) Quantification of Sox9 protein in  $\Delta N$ -positive SI epithelium compared to controls.** Upper panel: SDS-PAGE Western blotting using PSI whole cell extracts from control and  $\Delta N$  mice (n=3/group) showing Sox9 protein expression. Lower panel: Quantification of Sox9 protein expression normalized to vinculin. \*:  $p < 0.05$ , error bars = SEM. **(D - I) Sox9 protein is co-expressed with EGFP (equivalent to active nuclear NF- $\kappa$ B in the cell).** IF using anti-EGFP and Sox9 antibody co-staining on sections of PSI of  $\kappa\kappa$ -EGFP reporter mice (n=3/group). Yellow arrow heads point to cellular co-localization of Sox9 expression and NF- $\kappa$ B activity (EGFP expression). Nuclear counterstain: DAPI. Scale bars = 10 $\mu$ m.
