Summary Statement

Hemocyte-ablation in *Drosophila melanogaster* with a novel strong hemocyte-specific driver causes pupal lethality under germ-free conditions

Abstract

Proven roles for hemocytes (blood cells) have expanded beyond the control of infections in *Drosophila*. Despite this, the critical role of hemocytes in post-embryonic development has long thought to be limited to control of microorganisms during metamorphosis. This has previously been shown by rescue of adult development in hemocyte-ablation models under germ-free conditions. Here we show that hemocytes have a critical role in post-embryonic development beyond their ability to control the microbiota. Using a newly generated, strong hemocyte-specific driver line for the GAL4/UAS system, we show that specific ablation of hemocytes is early pupal lethal, even under axenic conditions. Genetic rescue experiments prove that this is a hemocyte-specific phenomena. RNA-seq data suggests that dysregulation of the midgut is a prominent consequence of hemocyte ablation in larval stages, resulting in reduced gut lengths. Dissection suggests that multiple processes may be affected during

metamorphosis. We believe this novel role for hemocytes during metamorphosis is a major finding for the field.

Introduction

Drosophila melanogaster is an important model to study both the immune and non-immune related functions of blood cells (hemocytes) (Mase et al., 2021). Plasmatocytes are macrophage-like cells (~95% of larval hemocytes) that secrete signalling peptides, antimicrobial peptides, and extra-cellular matrix (ECM) proteins in addition to phagocytosing microorganisms and apoptotic cells (Olofsson and Page, 2005, Braun et al., 1998). Crystal cells (~5% of larval hemocytes) express high levels of pro-phenoloxidases, which catalyse the extracellular production of melanin and toxic by-products upon cell lysis; critical for wound closure and immunity (Binggeli et al., 2014). Lamellocytes, rarely found in healthy larvae, transdifferentiate in large numbers from plasmatocytes to encapsulate large pathogens (Sinenko et al., 2011). Recent single-cell RNA sequencing studies have shown greater heterogeneity in these cell types (Cattenoz et al., 2020, Tattikota et al., 2020, Coates et al., 2021).

Two waves of hematopoiesis occur in *Drosophila* development. Embryonic hemocytes originate from the head mesoderm; they are long-lived, many surviving into the adult stage (Tepass et al., 1994). Larval hematopoiesis occurs in the lymph gland and in hematopoietic pockets (HP), patches of sessile hemocytes associated with the larval cuticle. HP are the main source of increasing numbers of circulating hemocytes during larval development (Leitao and Sucena, 2015); whereas hemocytes from the lymph gland are released into circulation at early metamorphosis (Jung et al., 2005).

Genetic ablation studies that aimed to identify the importance of hemocytes in *Drosophila* were first performed over a decade ago (Charroux and Royet, 2009, Nehme et al., 2011, Defaye et al., 2009, Shia et al., 2009, Arefin et al., 2015). 60-75% reduction in larval hemocyte numbers was achieved by hemocyte-specific expression of pro-apoptotic transgenes, ablating cells through programmed cell death. Multiple studies showed a reduction in eclosion of adult flies of up to 60%; interestingly however, eclosion rates were rescued when larvae were reared with antibiotics or under germ-free conditions (Arefin et al., 2015, Charroux and Royet, 2009, Defaye et al., 2009, Shia et al., 2009). This suggested

control of microorganisms by hemocytes is critical during metamorphosis, and that hemocyte functions beyond immunity are non-essential for post-embryonic development (Charroux and Royet, 2009, Shia et al., 2009, Arefin et al., 2015, Defaye et al., 2009). In contrast, ablation of embryonic hemocytes is embryonic lethal, independent of control of microorganisms (Defaye et al., 2009, Shia et al., 2009).

In this study, we designed an improved *Drosophila* hemocyte-specific larval and adult driver line, Hml^{P2A} -GAL4. Using Hml^{P2A} -GAL4 driven apoptosis, we almost completely ablated hemocytes in the larvae. We show for the first time that hemocytes are essential for the development of adult stage flies, independent of control of the microbiota. RNA-seq data shows a striking upregulation of genes in the midgut of 'hemoless' larvae, and points to a critical role of hemocytes in regulating intestinal development and beyond.

Results & Discussion

Hml^{P2A}-GAL4 is a hemocyte-specific driver

Currently, the most widely used hemocyte-specific driver in larvae and adults is Hml^{Δ} -GAL4, which utilises 840 bp of the Hml enhancer (Sinenko and Mathey-Prevot, 2004). To generate an optimised enhancer element, we included the first 9 exons of Hml followed by a P2A self-cleaving sequence upstream of GAL4 (Hml^{P2A} -GAL4) (Fig. S1). Transgenic flies were generated at two landing-sites, attP40 and attP2.

To analyse expression, we combined Hml^{P2A} -GAL4 driving expression of EGFP (Hml^{P2A} >GFP) with $srp^{\rm Hemo}$ -QF2 driving mCherry ($srp^{\rm Hemo}$ >mCherry) (Fig. 1 and Fig. S2). $srp^{\rm Hemo}$ -QF2 derives from the serpent enhancer and drives expression in embryonic and larval hemocytes (Gyoergy et al., 2018) as well as pericardial nephrocytes and Garland cells (Das et al., 2008). Consistent with the reported onset of Hml expression during $1^{\rm st}$ larval instar (Defaye et al., 2009), $srp^{\rm Hemo}$ positive ($srp^{\rm Hemo}$ +) hemocytes in stage 17 embryos were mostly $Hml^{\rm P2A}$ negative ($Hml^{\rm P2A}$ -), although faint expression was detected in some cells (Fig. S2B). In late $1^{\rm st}$ larval instar (Fig. 1A-C) $Hml^{\rm P2A}$ expression overlapped with $srp^{\rm Hemo}$ expression in peripheral HP with some hemocytes still $Hml^{\rm P2A}$ - (Fig. 1B), and independent of $srp^{\rm Hemo}$ in the developing lymph gland (Fig. 1C). In late $3^{\rm rd}$ larval instar wandering stage (WS) (Fig. 1D-F), $Hml^{\rm P2A}$ + hemocytes were a mixture of $srp^{\rm Hemo}$ - and $srp^{\rm Hemo}$ + (Fig. 1E); lymph gland $Hml^{\rm P2A}$ + hemocytes were all $srp^{\rm Hemo}$ - (Fig. 1F). This correlates with previous reports that $srp^{\rm Hemo}$ is

expressed in hemocytes solely deriving from embryonic hematopoiesis (Bruckner et al., 2004). Overlap between Hml^{P2A} and srp^{Hemo} was restricted to hemocytes during the entire development and we did not observe Hml^{P2A} expression outside hemocytes (Fig. S2).

We next used hemocyte-specific antibodies to determine the coverage of Hml^{P2A} expression in hemocytes (Fig. 1G-L). The overlap between Hml^{P2A} expression and the plasmatocyte marker Nimrod C1 (Kurucz et al., 2007a) was >80% (Fig. 1G & H). Overlap with the panhemocyte marker Hemese (Kurucz et al., 2003) was ~98% (Fig. 1I & J). Similar to the *in vivo* data, all srp^{Hemo} + hemocytes were Hml^{P2A} + in WS-larvae, whereas only ~60% of Hml^{P2A} + hemocytes were srp^{Hemo} + (Fig. 1K & L). Very few lamellocytes were detected using the L1 antibody (Kurucz et al., 2007b), but of those detected, 95% were Hml^{P2A} + (Fig. 1M).

Hml^{P2A} -GAL4 is a stronger driver than Hml^{Δ} -GAL4

To compare the expression strength of Hml^{P2A} -GAL4 and Hml^{Δ} -GAL4 we assayed extracted hemocytes from Hml^{P2A} >GFP and Hml^{Δ} >GFP WS-larvae by flow cytometry (Fig. S3A). Hml^{P2A} >GFP (attP2 and attP40) hemocytes showed ~4-fold higher EGFP expression than Hml^{Δ} >GFP hemocytes, which was consistent with microscopy of WS-larvae and adults (Fig. S3B & C).

To compare the efficiency of hemocyte ablation between Hml^{P2A} -GAL4 and Hml^{Δ} -GAL4 we used them to drive expression of the pro-apoptotic gene reaper (rpr) or the mouse BCL2-associated X protein gene (Bax). Consistent with previous studies (Arefin et al., 2015, Charroux and Royet, 2009, Defaye et al., 2009, Shia et al., 2009), Hml^{Δ} -GAL4 induced significant but incomplete ablation of total blood cells or crystal cells (Fig. 2A & B, Fig. S3D-F). Hml^{P2A} -GAL4 (attP2) improved the efficiency of rpr mediated ablation to >99% in both cases (Fig. 2A & B). We verified ablation of plasmatocytes by staining for Nimrod C1 and Hemese (Fig. 2C). We also identified Hemese-positive lamellocytes by cell morphology, but observed no depletion despite Hml^{P2A} expression in lamellocytes (Fig. 1M). In contrast to previous studies with Hml^{Δ} -GAL4, we neither observed increased lamellocyte numbers, nor melanotic masses in Hml^{P2A} >rpr or Hml^{P2A} >Bax larvae (n>20) (Arefin et al., 2015, Defaye et al., 2009).

To follow the dynamics of hemocyte ablation *in vivo* we combined $Hml^{P2A} > rpr$ with $srp^{\text{Hemo}} > m$ Cherry. The ablation pattern correlated with expression analysis (Fig. 2D). Few $srp^{\text{Hemo}} +$ hemocytes were still detected by the end of 1st larval instar (24 h ALH), but from late 2nd instar onwards (48 h ALH) we only detected cell remnants. Hemocytes associate with multiple tissues (Cox et al., 2021, Gyoergy et al., 2018, Ayyaz et al., 2015). To address the ablation of tissue-resident hemocytes we dissociated WS-larvae and assessed cells by flow cytometry (Fig. 2E). $srp^{\text{Hemo}} +$ hemocytes comprised ~5% of live single cells in controls, but were eliminated in $Hml^{P2A} > rpr$ larvae. Together, this shows that Hml^{P2A} allows almost complete ablation of plasmatocytes and crystal cells.

Hemocyte ablation with Hml^{P2A} -GAL4 is pupal lethal under germ-free conditions

Previous Hml^{Δ} -GAL4 ablation studies showed a reduction in eclosion rates that were rescued by antibiotic treatment or germ-free (GF) conditions (Arefin et al., 2015, Charroux and Royet, 2009, Defaye et al., 2009, Shia et al., 2009). Given the improved ablation rate of hemocytes using Hml^{P2A} -GAL4 we revisited this observation (Fig. 3, Fig. S4). First, we compared survival rates between Hml^{P2A} -GAL4 and Hml^{Δ} -GAL4 driven hemocyte ablation. Eclosion rates of Hml^{Δ} -rpr and Hml^{Δ} -rpr and requiver-GAL4 and Royet, 2009, Defaye et al., 2009, Shia et al., 2009), but still statistically significant (Fig. 3A, Fig. S4B). Strikingly, eclosion rates of requiver-rpr and requiver-r

Next, we analysed lethality in more detail comparing both Hml^{P2A} driver lines (Fig. 3C-E, Fig. S4C & D). Larval survival was not affected under GF and conventional conditions (Fig. 3C, Fig. S4C). Larval development was extended for all genotypes under GF conditions, but relative to controls, pupariation of $Hml^{P2A} > rpr$ was only slightly delayed under conventional conditions (Fig. 3C, Fig. S4C). Eclosion rates were ~10% for $Hml^{P2A} > rpr$ (attP40) and <1% for $Hml^{P2A} > rpr$ (attP2) (Fig. 3D). The eclosion rate for $Hml^{P2A} > rpr$ (attP40) was reduced to ~2% under conventional conditions (Fig. S4C). To further characterize pupal lethality we

scored the end-point of pupal development into three categories (Bainbridge and Bownes, 1981); arrest before pupal stage P8 (light pupae, Fig. 3D & E), between P8-P14 (pharate, Fig. 3D & E) or during P15 (failed eclosion, Fig. 3D). The majority of 'hemoless' pupae died before P8 with no visible eye coloration. For Hml^{P2A}>rpr (attP2) this was almost 100% and not affected by GF conditions. For $Hml^{P2A} > rpr$ (attP40) GF conditions reduced the fraction of pupae that died during pharate stages (P8-14, Fig. 3D & E), whilst increasing the number of failed eclosions and adults. This suggested that GF conditions primarily affected late pupal development. All surviving adults showed a non-inflated wing phenotype and we found residual hemocytes in escapers from $Hml^{P2A} > rpr; srp^{Hemo} > mCherry (Fig. S4D)$. Together this indicated that $Hml^{P2A} > rpr$ (attP2) causes a slightly stronger, more penetrant phenotype, which we further analysed. $Hml^{P2A} > rpr$ (attP2) pupae showed defects during pupariation (non-retracted mouth hooks, non-everted anterior spiracles) and by 24 h post-pupariation 95% of pupae (n=101) had a large posterior gas bubble (Fig. S4E). This likely reflects failure to complete stage P4 (ii), the 'moving bubble' stage (Bainbridge and Bownes, 1981). We confirmed by dissection that legs/wings were partially everted, but malpigian tubules had not yet formed compact white structures as seen in controls 24 h post-pupariation. In summary our data suggests, that 'hemoless' pupae die during early metamorphosis.

Eclosion rates are rescued with hemocyte-specific expression of GAL80

In order to minimise the chance that pupal lethality in our ablation experiments was caused by off-target expression of Hml^{P2A} -GAL4, we performed genetic rescue experiments with hemocyte-specific expression of the GAL4 inhibitor, GAL80. Eclosion rates of Hml^{P2A} -rpr (attP2) were rescued by Hml^{Δ} -QF2 driving QUAS-GAL80 (Hml^{Δ} -GAL80), showing that Hml^{P2A} -GAL4 has no critical off-target expression compared to the original Hml driver (Fig. 3F, Fig. S4F). We then used $srp^{\rm Hemo}$, either directly driving GAL80 ($srp^{\rm Hemo}$ -GAL80) or via $srp^{\rm Hemo}$ -QF2 ($srp^{\rm Hemo}$ -GAL80) to rescue Hml^{P2A} -rpr (attP2) or Hml^{P2A} -rpr (attP40), respectively (Fig. 3F, Fig. S4F). Based on the observation that $srp^{\rm Hemo}$ and Hml^{P2A} -rpr lethality is caused by hemocyte ablation.

Hemocyte ablation leads to dysregulation of midgut expressed genes

To analyse the consequences of hemocyte ablation before lethality in early pupal stages, we generated RNAseq datasets for whole WS-larvae and isolated plasmatocytes and classified transcripts as 1) not expressed in plasmatocytes, 2) similarly present in both datasets (shared)

or 3) enriched in plasmatocytes (Fig. 4A). To address potential systemic responses we further analysed tissue-specific enrichment of transcripts based on data available at FlyAtlas2 (Leader et al., 2018) (Fig. S5B). Plasmatocyte-enriched transcripts were detected to a variable degree in multiple tissues (Fig. S5B), reflecting either low-level expression outside plasmatocytes or the presence of plasmatocytes in these tissues (Ayyaz et al., 2015, Cattenoz et al., 2020, Cox et al., 2021). Known hemocyte-specific transcripts (*Hml*, *He*, eater, *Pxn* and *NimC1*), were detected as plasmatocyte-enriched (Fig. 4A) and present in the larval carcass (Fig. S5B), likely due to the association of sessile hemocytes with the cuticle or lymph glands in the carcass. These transcripts were also significantly depleted in the differential expression analysis between $Hml^{P2A} > rpr$ and control larvae (Fig. 4B, and Table S1).

We could not identify a tissue specific response for downregulated transcripts, as only a minority of them were non-plasmatocyte (46/131, Fig S5C) and Gene Ontology (GO) analysis revealed phagocytosis as the only significantly enriched process or function. In contrast, upregulated transcripts were primarily comprised of non-plasmatocyte transcripts (131/170) and a majority of them was expressed in the midgut (Fig. 4C and Fig S5C). GO term analysis showed a strong enrichment of genes associated with chitin metabolism (Fig. 4C). To further analyse phenotypic differences in larval gut morphology, we dissected guts from WS-larvae and analysed them by electron (EM) and fluorescent microscopy. Larval gut lengths were significantly decreased in $Hml^{P2A} > rpr$ compared to control (Fig. 4D, Fig. S6A & B). However, we did not observe a striking difference in gut architecture by either EM or fluorescent microscopy (Fig. S6C & D). Dissected $Hml^{P2A} > rpr$ pupal guts 24 h post-pupariation resembled control guts from 12 h post-pupariation, which is approximately the time point when $Hml^{P2A} > rpr$ lethality starts (stage P4, Fig. S6E).

Taken together, we have shown an essential role for hemocytes in post-embryonic development beyond the control of microorganisms. Hemocyte ablation in our model starts in early larval development and appears to be complete by mid-larval stages. The main advantages of our model compared to previous system are improved transgene expression over Hml^{Δ} and higher specificity for hemocytes compared to srp^{Hemo} . In contrast to previous studies, we achieved depletion of hemocytes to <1% of control animals, which leads to pupal lethality that can no longer be rescued by germ-free conditions. One of these studies showed that hemocyte-derived signalling promotes basal and damage/infection induced proliferation of intestinal stem cells in adults but failed to detect a larval gut phenotype after ablation of

hemocytes with Hml^{Δ} (Ayyaz et al., 2015). The striking reduction in larval midgut length that we observed could indicate a similar developmental function of hemocytes, which was previously obscured by incomplete hemocyte ablation. However, we cannot exclude that lethality resulted from pleiotropic defects that we observed later in development.

A drawback of apoptosis-driven depletion of hemocytes is that the increase in apoptotic bodies may in itself induce a physiological response in the fly, including upregulation of immune-related genes (Arefin et al., 2015). In future studies it would be interesting to assess whether the genetic manipulation of specific hemocyte functions recapitulates pupal lethality, as seen when hemocyte migration is impaired in embryos (Matsubayashi et al., 2017).

Materials & Methods

Drosophila melanogaster Strains

Fly strains obtained from Bloomington Stock Centre were Hml^{Δ} -GAL4 (30139), UAS-2xEGFP (6874), UAS-rpr II (5824), UAS-rpr X (5823), srpHemo-QF2 (78365), srpHemo-GAL80 (78366), Hml^{Δ} -QF2 (66468), QUAS-GAL80 (51950), QUAS-mCherry (5227) and attP2 (8622). The $P\{UAS$ -Bax. $G\}$ integration on chromosome II (UAS-Bax) was a gift from Carla Saleh (Department of Virology, Institute Pasteur) and balanced with CyO, $P\{ActGFP\}JMR1$. The Hml^{P2A} -GAL4 lines were constructed in this study. Genotypes derived from these strains are outlined below (for male animals the second X chromosome was Y).

Generation of Hml^{P2A}-GAL4 Flies

A 3477bp fragment was synthesised (Eurofins) containing 840bp upstream of the *Hml* transcription start site and the *Hml* transcript up to the end of exon 9 (bp13845367 – bp13848766, dm6), directly followed by an *Avr*II site, a P2A translation skip sequence, and a *Xba*I site. The *Xba*I site was used to insert the GAL4 coding sequence from pGawB followed by a SV40 3'UTR from pUASt. The construct was assembled in a backbone derived from pDESTR3R4-\$\phiC31attB\$ (Gunesdogan et al., 2010), containing a w^{+mc} transformation marker and attB integration sequence. Transgenic lines were generated in *P{CaryP}attP40* and *P{CaryP}attP40* and *P{CaryP}attP40* and *P{Hml-GAL4.P2A}attP2* integrations were crossed out to remove integrase transgenes before further use.

Controlled density cultures

Cultures were raised on rich cornmeal molasses food (25 g Agar-Agar, 14.4 g yeast, 8 g soy flour, 64 g yellow cornmeal, 64 g light malt extract, 17.6 g molasses, 6 ml propionic acid, 0.8 g Nipagin per litre). For germfree cultures medium was autoclaved before adding propionic acid. For antibiotic treatment 5 mg/ml Ampicillin (Sigma) + 5 mg/ml Kanamycin (Sigma) was added before pouring the food at ~50°C. For controlled density cultures, embryos were collected on apple juice agar plates at 25°C in a 12 h light/dark cycling incubator. 1st instar larvae were picked from plates and seeded at 100 or 120 larvae per vial. Conventional/antibiotics cultures contained live yeast. For staged cultures 1st instar larvae that hatched within a 5 h time window were seeded. Larvae were raised at 25°C in a 12 h light/dark cycling incubator.

Larval/Pupal survival assays

For crosses involving $P\{UAS-rpr.C\}14$, larval survival was scored as fraction of pupae formed from seeded 1st instar larvae. For crosses involving $P\{UAS-Bax.G\}$, larval survival

was scored relative to internal control genotype ($Hml^{P2A} > Bax\ per\ Hml^{P2A} > Bal$). For crosses involving $P\{UAS\text{-}rpr.C\}14$, pupal survival was scored as fraction of pupae that developed to adults (or a specific pupal stage) from all pupae that were formed in a vial. For crosses involving $P\{UAS\text{-}Bax.G\}$, pupal survival was scored as number of adults relative to internal control genotype ($Hml^{P2A} > Bax\ per\ Hml^{P2A} > Bal$). From this cross we expected 1:1 $Hml^{P2A} > Bax\ :\ Hml^{P2A} > Bal$ adults if there was no effect in Bax expressing animals. The fraction of expected therefore was scored relative to balancer carrying animals. Since balancer chromosomes can to some degree reduce fitness, the fraction of expected can be higher than 1 in some cases. For analysis of pupariation timing, newly formed pupae were scored in 24 h intervals. Vials were left 1 week longer than eclosion was observed in control genotypes to check for late eclosing adults. All pupae that did not eclose were inspected and scored as light pupae (<stage P8), pharates (stage P8-P14) or failed eclosion (stage P15).

Germ-free cultures

Embryos were collected from crosses for 6 h at 25° C. Embryos were washed twice in a 100 µm cell-strainer with PBTx.01 (PBS, 0.01 % Triton-X100 (Sigma)) and transferred in 70 % ethanol in a clean bench in. After 5 min, embryos were dechorionated in 50:50 Clorax/water (2.5 % HOCl final) for 2 min and washed 3 times in sterile PBTx.01. For initial experiments (Fig. 2B, S4B) embryos were suspended in PBTx.01 and total number of embryos approximated by counting from an aliquot. An average of 100 embryos was seeded in sterile food vials by pipetting the respective amount of embryo suspension. For all other experiments embryos were transferred to sterile agar plates and hatched larvae were picked for a time window of 5 h using a Lynx EVO stereomicroscope (Vision Engineering) in a clean bench. To check for germ-free conditions 5 adults/pupae from each culture were homogenized in 100 μ l PBS and plated on YPD. Plates were sealed and incubated for 3 days at 30°C. Plates from conventional conditions were included with each plating showed a lawn of yeast/bacteria; germ-free cultures that showed any growth on plates were excluded from the analysis (<5% of cultures).

Hemocyte extraction by bleeding

Larvae were collected and extensively washed with water in 100 µm cell-strainers to remove debris followed by 5 min in 70 % ethanol. Sessile hemocytes were dislodged by extensively

rubbing the larvae with a paint brush. Larval cuticles were ripped open from posterior to anterior using fine forceps and hemocytes bled out.

Hemocyte quantification and staining

For hemocytometer counts, larvae were bled into 20 µL PBS, 5mM EDTA, 1:250 protease inhibitor cocktail (Sigma) on parafilm. For antibody staining, five larvae were bled into 200 μL Schneider's medium (Sigma) with 10mM N-Acetyl-L-Cysteine (Sigma) in 8 well μ-slide dishes (ibidi). Cells were allowed to adhere for 30 min, washed twice with Schneider's medium and fixed for 10 min with 4 % paraformaldehyde (Sigma), 50 mM EDTA in PBS. Samples were washed with PBTx (PBS, 0.1 % Triton-X100) and blocked for 30 min with 10 % goat serum (Sigma) in PBTx (PBTx-GS). Primary antibodies 1:60 in PBTx-GS (anti-Nimrod C1 clones P1a/P1b, anti-Hemese clone H2, anti-Attila clones L1a/L1b/L1c, gift from Istvan Ando, Szeged, Hungary (Kurucz et al., 2007b)) were incubated over night at 4°C. After three washes with PBTx, samples were incubated with AlexaFluor 647 goat anti mouse (1:500, Abcam, ab150115) and 0.1 mg/ml RNase A (Sigma) in in PBTx-GS for 2 h at room temperature. After two washes with PBTx, samples were overlaid with 5 µM DAPI (Roth) in PBTx. Entire wells were scanned with a Leica SP8 confocal microscope and images analysed in Fiji. For quantification of ablation experiments, images were first segmented based on antibody staining. Within antibody positive area, segmentation based on DNA staining with particle limits 5-50 µm² was used to determine cell numbers. Lamellocytes were selected manually from scans of entire wells stained with anti-Hemese antibody and checked for a minimum single cell size of 300 µm², which was ~2.5 times larger than the average size of Hemese positive cells (~120 µm²). For quantification of co-expression, images were segmented based on DNA staining with a lower area limit of 20 µm² and signal thresholds were adjustment to yield an average area of 55 µm² over all detections. Analysis was then limited to particle sizes between 28-83 µm². Within these regions, average signal intensities for EGFP, mCherry and Alexa 647 were measured. Thresholds for positive detections were set in R based on the analysis of signal histograms. For crystal cell quantification larvae were picked and washed in PBS and then heat-shocked at 65°C for 10 min, which causes the crystal cells to melanise and turn black. For each larva a dorsal and ventral image was taken using a Leica M205 stereomicroscope. Crystal cells were counted manually.

Hemocyte Flow Cytometry

For analysis of EGFP expression, 50 larvae were bled into the lid of a 1.5 ml Eppendorf tube containing 200 µl Schneider's medium, 1:250 protease inhibitor cocktail (Sigma). Carcasses were removed and the cell solution was transferred to a 1.5 ml Eppendorf tube containing 800 µl fresh medium and passed through at 70 µm Flowmi tip filter (Sigma). Cells were analysed on a MACSQuant Analyser (Miltenyi Biotec). For the analysis of tissue-associated hemocytes, 20 larvae were washed in water and homogenized in 1 ml of PBS with 20-30 strokes in a 1 ml loose fit Dounce. The suspensions were passed through a 40 µM cell-strainer by centrifugation into Schneider's medium containing 25 % fetal calf serum, 2 mM EDTA at 1500g for 10 min. The supernatant was discarded and the pellet resuspended in 1 ml Schneider's medium and analysed using CytoFLEX (Beckman). Data was analysed by FlowJo software.

Live imaging experiments

Imaging of embryos and larvae was performed in Frame-Seal Hybridization Slide Chambers, (15 x 15 mm, BioRad) filled with a gel of 30 % (w/v) OptiPrep (Sigma) and 30 % (w/v) Pluronic F-127 (Sigma) in PBS on a glass slide closed with a coverslip. The gel was kept liquid at 4°C and solidified at room temperature. Embryos were dechorionated in 50:50 Clorax:water (2.5% HOCl final) for 3 min, washed with embryo saline (0.7% NaCl, 0.01% Triton-X100) and glued to the coverslip that sealed the chamber. Larvae were washed in embryo saline, anesthetized with Ether according to published protocol (Kakanj et al., 2020), and glued to the slide side of the chamber. Adult flies were anesthetized with Ether and glued to a glass slide. Imaging of adults and whole larvae was done with a Leica M205 stereomicroscope; embryos and larval details were imaged on a Leica SP8 confocal microscope.

Larval and pupal gut analysis

Larvae were washed in water and transferred to either Schneider's medium or PBS for dissection. Intact guts were allowed to contract for 30 min and fixed for 10 min in 4 % paraformaldehyde, 50mM EDTA in PBS. For determination of gut length, guts were mounted in fixative in Frame-Seal Hybridization Slide Chambers, imaged with a Leica M205 stereomicroscope and analysed in Fiji. For fluorescent staining, guts were washed in PBTx and stained in PBTx, 1 mg/ml RNase A, 5 μ M DAPI, 300 nM Alexa Fluor 647 Phalloidin

(Thermo Fischer) for 30 min. Samples were mounted in Frame-Seal Hybridization Slide Chambers and imaged with a Leica SP8 confocal microscope. For electron microscopy midguts were post-fixed with 2.5 % glutaraldehyde (Electron Microscopy Sciences) and embedded in groups into small cubes of low melting agarose. These were then further post-fixed with 0.5 % Osmium-tetroxide and tannic acid, contrasted with Uranyl-acetate, dehydrated in a graded ethanol series, and infiltrated in Polybed (Polysciences). The cubes were placed in flat embedding molds with Polybed. After polymerization, the blocks were trimmed to the desired sectioning plane and sections were cut at 60 nm. Specimen were analysed in a LEO 906E transmission electron microscope (Zeiss, Oberkochen. DE) at 100kV, equipped with a side-mounted digital camera (Morada, SIS-Olympus, Münster, DE)

Plasmatocyte RNAseq

OreR larvae were raised at controlled density as described above. Plasmatocytes were extracted as described above into complete media in tissue-culture treated dishes (Schneider's medium with 10% FCS and 10 mM N-Acetyl-L-Cysteine). 80 larvae were bled for each sample. The larval carcasses were then removed and the plasmatocytes were allowed to attach for 10-15 min. Afterwards, plasmatocytes were washed 4 times with PBS and lysed in 900 µl TRIzol. Samples were moved to fresh prespun phase lock heavy tubes (5PRIME). 250 μl chloroform was added to each sample, mixed thoroughly and centrifuged (12000 g, room temperature, 15 min). The upper aqueous phase was moved to a fresh DNA LoBind tube, and mixed with 550 µl isopropanol and 1 µl glycogen (20 mg/ml, RNAse free). Samples were mixed by inverting and incubated for 30 min in the freezer at -20°C. Samples were centrifuged (16000 g, 4°C, 10 min) and the supernatant was removed carefully without disrupting the pellet. The pellet was resuspended in 100 µl ultra-pure water with 300 mM sodium acetate and 1 µl glycogen (20 mg/ml, RNAse free). 300 µl EtOH was added and the sample was incubated for 20 min at -20°C, centrifuged (16000 g, 4°C, 10 min) and the supernatant discarded. The pellet was washed 2 times by adding 1 ml 70 % EtOH (prepared with ultra-pure water), each time spinning down the pellet (16000 g, 4°C, 3 min). Afterwards all supernatant was drained and the pellet was dried until no liquid was visible. The pellet was then resuspended in 15 µl of ultra-pure water and stored at -80°C. Libraries from samples were generated at the Max Planck Genome Centre in Cologne using the NEB Next Ultra II Directional RNA library kit with polyA mRNA enrichment from ~100 ng total RNA. Libraries were pooled and sequenced to a minimum of 16 million uniquely mapped single end 150 bp reads per sample at the Max Planck Genome Centre in Cologne.

Larval RNAseq

Hml^{P2A}-GAL4 in attP2 or control P{CaryP}attP2 males were crossed to UAS-rpr X virgins and larvae were raised as described above. 10 male larvae were collected at 3rd instar wandering stage per sample across independent replicates and snap-frozen in liquid nitrogen. Larvae were transferred to Lysing Matrix E homogenization tubes with 1ml of TRIzol and ruptured on high settings in a FastPrep tissue homogenizer (MP Biomedicals). The supernatant was transferred to a fresh tube and spun down for 2 min at max speed. 800 µl of the TRIzol sample was transferred to a fresh prespun phase lock heavy tube and 200 µl Chloroform was added. Phases were separated by spinning at 12000 g, 15 min, 4°C. The upper aqueous phase was transferred to a fresh tube and mixed with 500 µl isopropanol. The resulting mix was spun at 20000 g, 15 min, 4°C. All supernatant was drained and the pellet resuspended in 30 µl DNAse solution (Ambicon, final conc. 0.2 U/µL) and incubated for 1 h at 37°C. RNA was purified using the RNeasy Plus kit (Qiagen) by adding 270 µl RTL buffer and isolated according the manufacturer's instructions. RNA concentration was determined by Nanodrop and integrity was checked by Bioanalyzer. Libraries from samples were generated at the Max Planck Genome Centre in Cologne using the NEB Next Ultra II Directional RNA library kit with polyA mRNA enrichment from ~100ng total RNA. Libraries were pooled and sequenced to a minimum of 10 million uniquely mapped 2x75bp paired end reads per sample at the Max Planck Genome Centre in Cologne.

RNA data mapping and analysis

The reference genome fasta sequence file of the Berkeley Drosophila Genome Project assembly dm6 and the related gtf genome annotation file for dm6 of ensembl release 91 (dm6.91) were downloaded from ensembl (www.ensmbl.org) (Zerbino et al., 2018). A reference genome index was generated using dm6.91 using STAR-2.7.0e (Dobin et al., 2013) and used to map the fastq files. Quality control of RNA-seq mapping was performed using RSeQC (Zhang et al., 2021). All quality control files for FastQC, STAR mapping, and RSeQC were aggregated and visualized using MultiQC (Ewels et al., 2016) and all data was checked to make sure the library and sequencing was of good quality. Once a data set passed quality control, the gene level read counts were determined from bam files using the subread package (Liao et al., 2013). The gene level read counts were then loaded into R. For PCA analysis the matrix of gene level read counts was transformed using the DESeq2 (Love et al., 2014) rlog function, from which the 1000 most variant genes were selected, PCA analysis was performed using the stats package prcomp function. For differential expression analysis,

gene level read counts were processed using the edgeR package (Robinson et al., 2010) with the quasi-likelihood general linear model approach according to the manual. GO Term enrichment was performed using GOrilla (http://cbl-gorilla.cs.technion.ac.il/) (Eden et al., 2009) testing enrichment of regulated protein coding gene sets against all genes detected in the experiment

Tissue enrichment analysis

All available data sets for protein coding genes detected in the RNAseq experiments were downloaded as text files from the web interface of FlyAtlas2 (http://flyatlas.gla.ac.uk/FlyAtlas2/index.html?page=home#). From these files tissue enrichments of individual transcripts were extracted, leaving out the enrichment in Garland cells since no documentation was available on how these cells were purified. The enrichment values were scaled in R and the resulting z-scores visualized as heatmaps after k-means clustering.

Data Availabilty

RNA-seq data of hemocyte-ablated larvae and of primary plasmatocytes is available on ArrayExpress (E-MTAB-11095 and E-MTAB-10759 respectively).

Acknowledgements

The authors would like to thank the Max Planck Sequencing Center for the library preparation and sequencing, Istvan Ando for the hemocyte antibodies, and Carla Saleh for the UAS-*Bax* fly stock.

Competing Interests

The authors declare no competing interests.

Funding

All of the authors were supported by core funding from the Max-Planck-Gesellschaft.

Figures

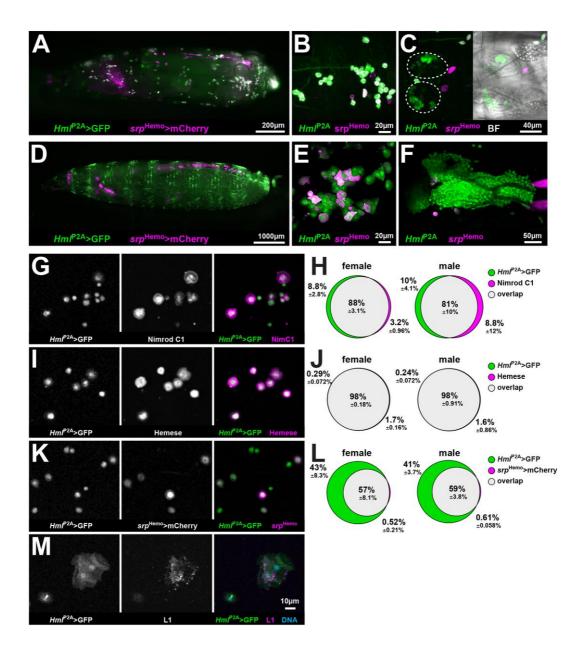

Fig. 1. Hml^{P2A}-GAL4 is a hemocyte-specific driver

(A-F) Fluorescent microscopy of Hml^{P2A} >GFP (attP40); srp^{Hemo} >mCherry 1st instar (A-C) and 3^{WS-larvae} (D-F). Whole animals (A & D); maximum projections of image stacks including peripheral hematopoietic pockets (B & E) or developing lymph gland (C & F). BF indicates bright field images.

(I-M) Fluorescent microscopy analysis of hemocytes extracted from Hml^{P2A} >GFP (attP40); srp^{Hemo} >mCherry WS-larvae stained with plasmatocyte-specific (Nimrod C1), pan-hemocyte (Hemese) or lamellocyte-specific (L1) antibodies. Euler diagrams show overlap of stainings

and Hml^{P2A} >GFP expression from $n \ge 3$ independent experiments, cells > 30,000 analysed. Overlap between L1 staining and Hml^{P2A} >GFP expression was 95% (SD 6.8%) from a total of 211 cells analysed from 5 independent experiments.

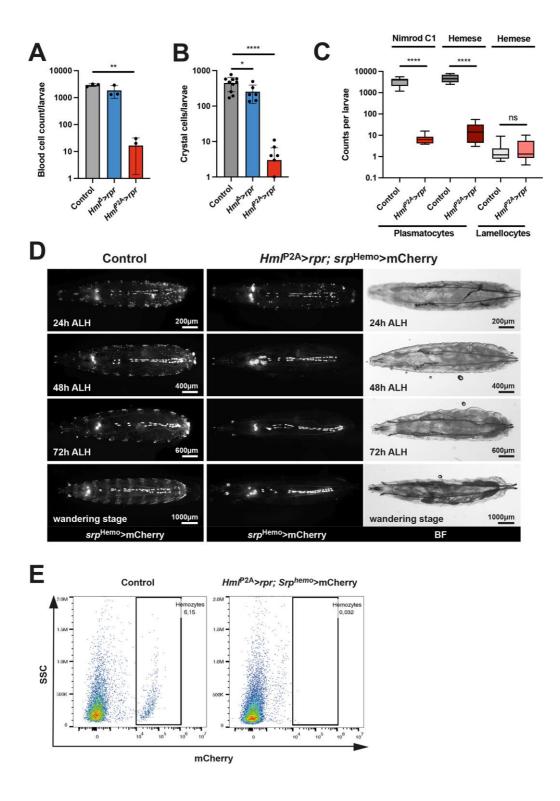

Fig. 2. Inducing apoptosis with $\mathit{Hml}^{P2A}\text{-}GAL4$ ablates virtually all plasmatocytes & crystal cells

(A–C) Hemocyte ablation in $Hml^{P2A} > rpr$ (attP2) 3rd instar WS-larvae.

Whole blood cell counts by hemocytometer (A), crystal cell counts by whole mount microscopy (B) and quantification based on staining with plasmatocyte-specific (Nimrod C1) or pan-hemocyte (Hemese) antibodies (C). Hemese positive lamellocytes were identified by

cell morphology. Each dot represents average counts from 5 animals (A & C) or a single animal (B). One-way ANOVA (A & B), and unpaired t-tests (C) were performed.

- (D & E) Hemocyte ablation in $Hml^{P2A} > rpr$ (attP40); $srp^{Hemo} > m$ Cherry larvae.
- (D) Whole mount fluorescence microscopy of late 1st (24 h ALH), late 2nd (48 h ALH), mid 3rd (72 h ALH) and WS-larvae. BF indicates bright field images.
- (E) Flow cytometry of cells from dissociated WS-larvae. Representative flow cytometry data from 3 independent experiments showing side scatter (SSC) and mCherry signals.

Controls: attP2>*rpr* (A&B), yw>*rpr* (C), *Hml*^{P2A}>GFP (attP40); *srp*^{Hemo}>mCherry (D & E). * p<0.03; ** p<0.002; *** p<0.0002; **** p<0.0001

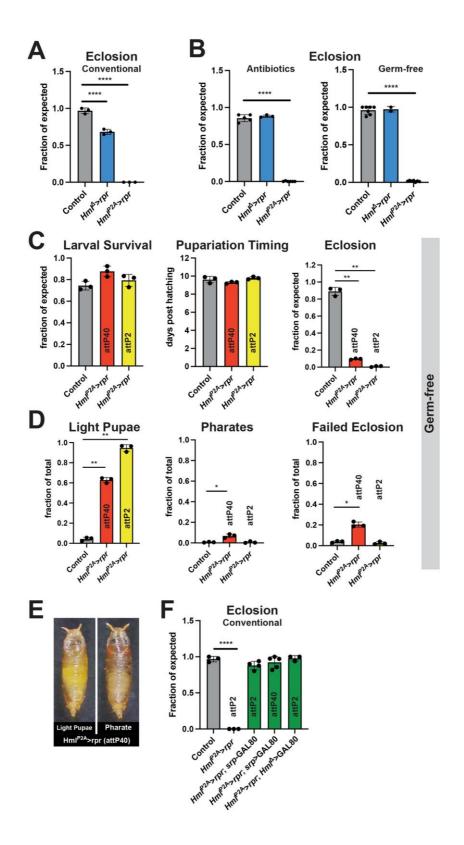

Fig. 3. Hemocyte ablation with Hml^{P2A} -GAL4 is pupal lethal under germ-free conditions (A & B) Eclosion rates of Hml^{Δ} >rpr and Hml^{P2A} >rpr (attP2) animals reared at controlled density under conventional conditions (A), on food containing 5 mg/ml Ampicillin and 5 mg/ml Kanamycin or under germ-free conditions (B). Eclosion rates were scored as number

of adults obtained from pupae that were formed per vial. Each dot represents an individual vial. One-way ANOVA were performed.

- (C & D) Comparison of Hml^{P2A} -GAL4 driver inserted in attP40 or attP2 based on controlled density cultures raised under germ-free conditions.
- (C) Larval survival was scored as pupae obtained from inoculated 1st instar larvae. Eclosion rates were scored as number of adults obtained from pupae that were formed, and pupariation timing as average over the day of pupariation for each pupae in one vial.
- (D) Pupal lethality was scored by determining the fraction of all pupae in a vial that terminated development before pupal stage P8 (light pupae), during stage P8-P14 (pharates) or in P15 (failed eclosion). Each dot represents an independent experiment including 4 vials each (C & D). One-way ANOVA were performed.
- (E) Representative images of dead pupae from $Hml^{P2A} > rpr$ (attP40) used to classify light pupae (before pupal stage P8) or pharate adult stage in (D).
- (F) Genetic rescue experiments with controlled density cultures raised under conventional conditions. $Hml^{P2A} > rpr$ (attP2) was rescued by srp^{Hemo} -GAL80, $Hml^{P2A} > rpr$ (attP40) by $srp^{Hemo} > GAL80$ or $Hml^{\Delta} > GAL80$. Eclosion rates were scored as number of adults obtained from pupae formed per vial, each dot represents one vial.

Controls: attP2>*rpr* (A, B, F), yw>*rpr* (C & D). * p<0.03; ** p<0.002; *** p<0.0002; **** p<0.0001

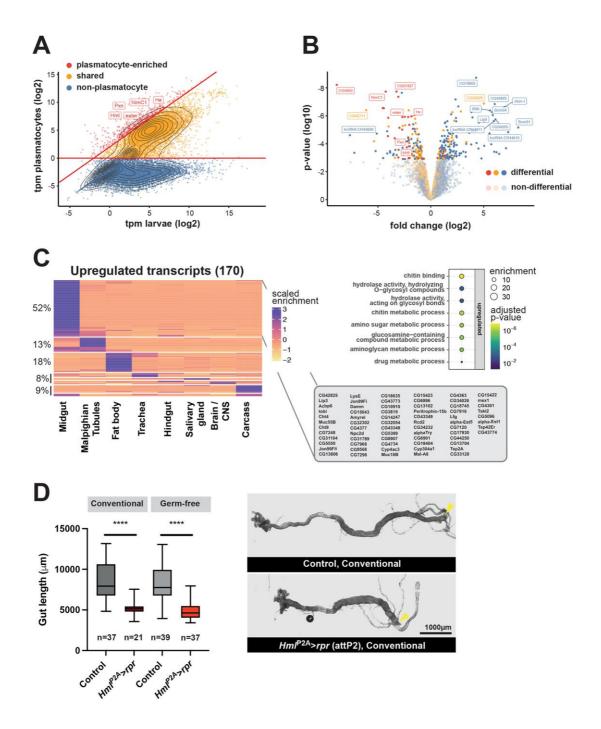

Fig. 4. RNAseq analysis of 'hemoless' WS-larvae.

(A) RNAseq expression analysis comparing relative expression strength (in tags per million, tpm) of transcripts in whole larvae with expression in larval plasmatocytes (both WS-larvae). Dots represent individual transcripts with overlaid density plot. Genes were classified as non-plasmatocyte (no or marginal expression in plasmatocytes, blue), shared (yellow) or plasmatocyte-enriched (>4 fold elevated in plasmatocytes, red). Hemocyte-specific transcripts are labeled.

- (B) Volcano plot illustrating differential transcriptome analysis of $Hml^{P2A} > rpr$ versus attP2 > rpr WS-larvae. Dots mark log2 fold changes and log10 differential expression p-values for individual genes. Genes are colored by assignment as in (A) with non-significantly regulated transcripts in lighter colors. The 15 most significantly regulated transcripts and hemocyte-specific transcripts are labeled.
- (C) Heatmap showing scaled tissue enrichment derived from FlyAtlas2 for upregulated protein coding transcripts. The fraction of transcripts within each k-means cluster is indicated in percent, the tissue type below the heatmap. A list of midgut specific transcripts that were upregulated in response to hemocyte ablation is shown. Gene ontology terms enriched within upregulated transcripts, p-values and enrichment effect sizes are indicated.
- (D) Midgut lengths from female $Hml^{P2A} > rpr$ (attP2) versus yw>rpr (Control) WS-larvae reared under conventional or germ-free conditions and dissected in Schneider's media (containing Ca²⁺). Midgut length was determined from the anterior of whole guts (left) to the attachment site of Malpigian tubules that mark transition to the hindgut (yellow arrowhead). Number of guts are indicated. One-way ANOVA were performed. * p<0.03; *** p<0.002; **** p<0.0001

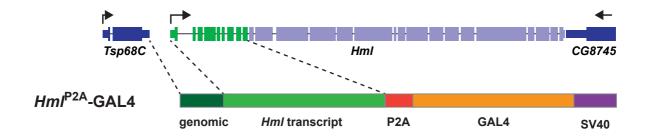

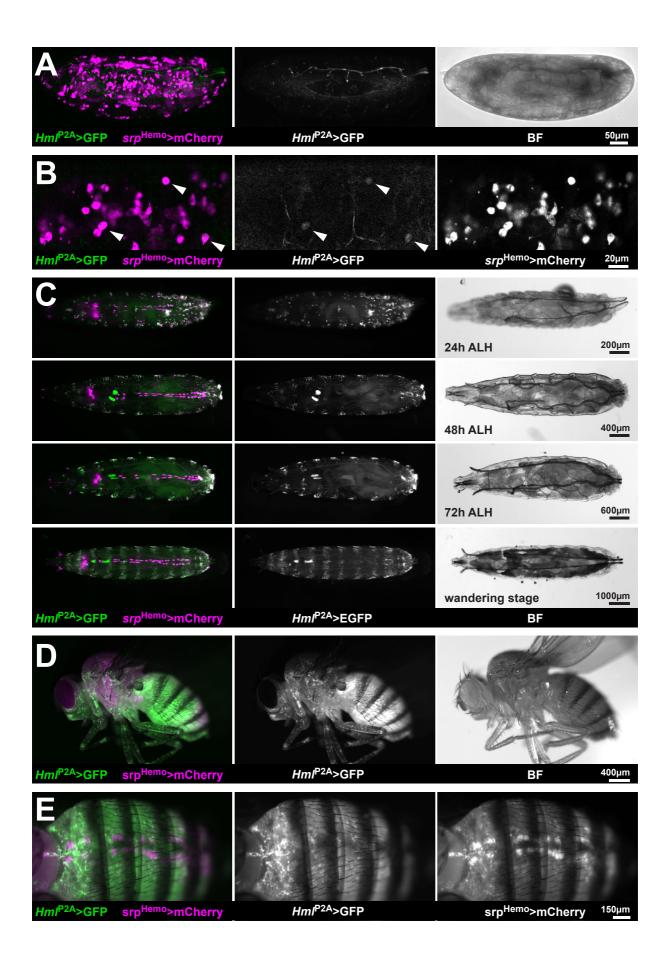

Fig. S1. Schematic of the Hml gene and the Hml^{P2A} -GAL4 construct.

- **Fig. S2.** (A-E) Fluorescent live imaging of *Hml*^{P2A}>GFP (attP40); *srp*Hemo>mCherry animals reared under conventional conditions and controlled density (B-E).
- (A) Maximum projection of an image stack that included ~80µm from the apical surface of a stage 17 embryo briefly before hatching, as indicated by air filled trachea.
- (B) Maximum projection of the hemocytes containing apical region of the embryo shown in (A). Arrowheads mark hemocytes with faint expression of *Hml*^{P2A}>GFP.
- (C) Dorsal view of whole larvae in a time course of late 1st instar (24h after larval hatching, ALH), late 2nd instar (48 h ALH), mid 3rd instar (72 h ALH) and 3rd instar WS larvae (wandering stage). BF indicates bright field images. Outside hemocytes, *srp*Hemo>mCherry is detected in some cells of unknown identity at the anterior of larva (left), in Garland cells that form a group of cells in the interior at about 20% larval length close to the brain, and in pericardial nephrocytes that form two rows of cells along the heart at the dorsal midline. We did not detect *Hml*^{P2A}>GFP expression in any of these regions.
- (D & E) Whole mount female fly (D) and close up of the abdomen of a female fly showing expression of *srp* Hemo>mCherry in adult pericardial nephrocytes (E).

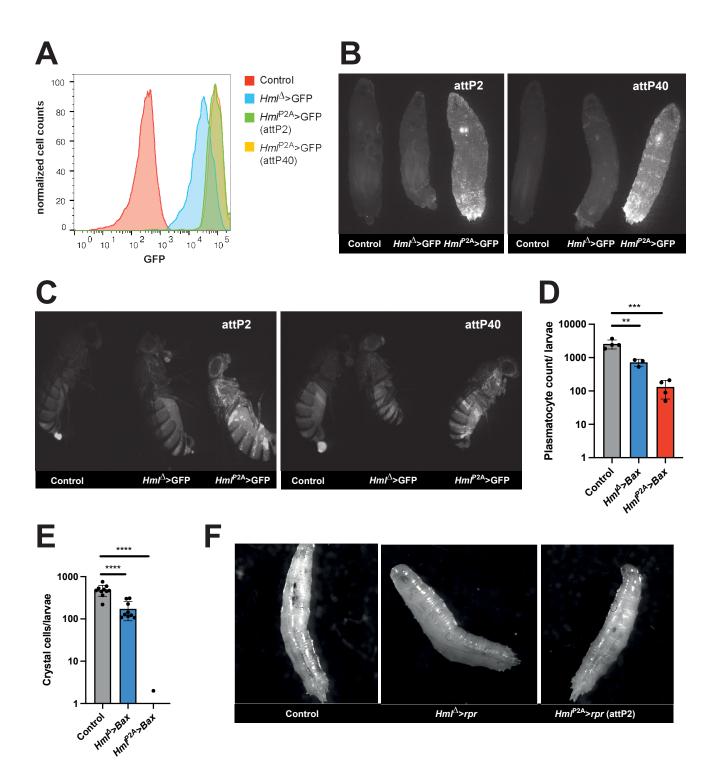

Fig. S3.

- (A) Flow cytometry analysis of extracted 3^{rd} instar WS larval hemocytes comparing the expression of $Hml^{\Delta}>GFP$, $Hml^{P2A}>GFP$ (attP2) and $Hml^{P2A}>GFP$ (attP40). Representative histogram from two independent experiments.
- (B) Whole mount fluorescence microscopy of 3^{rd} instar WS larvae comparing the expression of Hml^{Δ} >GFP to Hml^{P2A} >GFP (attP2; left) and Hml^{Δ} >GFP to Hml^{P2A} >GFP (attP40; right). Representative images from two independent experiments.
- (C) Whole mount fluorescence microscopy of adult females comparing the expression of Hml^{Δ} >GFP to Hml^{P2A} >GFP (attP2; left) and Hml^{Δ} >GFP to Hml^{P2A} >GFP (attP40; right). Representative images from two independent experiments.
- (D) Blood cell counts by hemocytometer from 3^{rd} instar WS larval from Bax mediated ablation in $Hml^{\Delta} > Bax$ or $Hml^{P2A} > Bax$ (attP2). One-way ANOVA was performed
- (E) Crystal cell counts by whole mount microscopy from 3^{rd} instar WS larvae after Bax mediated ablation in $Hml^{\Delta} > Bax$ or $Hml^{P2A} > Bax$ (attP2). Each dot represents counts from a single animal. One-way ANOVA was performed.
- (F) Representative images of 3^{rd} instar WS $Hml^{\Delta} > rpr$ or $Hml^{P2A} > rpr$ (attP2) larvae used for crystal cell quantification.

Controls: attP2>GFP (A-C), attP2>rpr (D & E), attP2>rpr (F).

* p<0.03; ** p<0.002; *** p<0.0002; **** p<0.0001

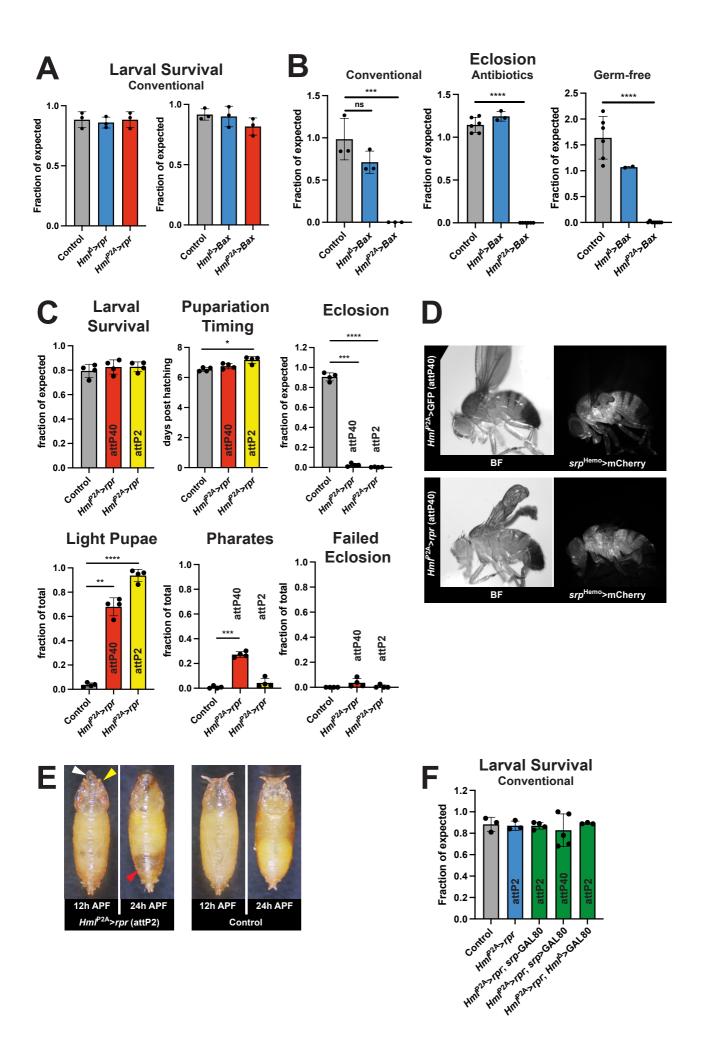

Fig. S4.

- (A) Larval survival from controlled density cultures under conventional conditions. Survival was scored as pupae obtained from inoculated 1st instar larvae for $Hml^{\Delta} > rpr$ or $Hml^{P2A} > rpr$ (attP2). For $Hml^{\Delta} > Bax$ or $Hml^{P2A} > Bax$ (attP2) survival was scored relative to the internal controls $Hml^{\Delta} > Bal$ or $Hml^{P2A} > Bal$ as fraction of GFP negative per GFP positive pupae (see materials and methods section for details). Each dot represents an individual vial. One-way ANOVA were performed.
- (B) Eclosion rates from $Hml^{\Delta}>Bax$ or $Hml^{P2A}>Bax$ (attP2) animals reared at controlled density under conventional conditions, on food containing 5 mg/mL Ampicillin and 5 mg/mL Kanamycin or under germ-free conditions. Eclosion rates were scored relative to the internal controls $Hml^{\Delta}>Bal$ or $Hml^{P2A}>Bal$ as fraction of Cy+ per Cy- adults, which can produce fractions of expected >1 (see materials and methods section for details). Each dot represents an individual vial. One-way ANOVA were performed.
- (C) Comparison of Hml^{P2A} -GAL4 driver inserted in attP40 or attP2 based on controlled density cultures raised under conventional conditions. Larval survival was scored as pupae obtained from inoculated 1st instar larvae. Eclosion rates were scored as number adults obtained from pupae that were formed and pupariation timing as average over the day of pupariation for each pupae in one vial. Pupal lethality was scored by determining the fraction of all pupae in a vial that terminated development before pupal stage P8 (light pupae), during stage P8-P14 (pharates) or in P15 (failed eclosion). Each dot represents an independent experiment including 4 vials each. Oneway ANOVA were performed.
- (D) Representative whole mount images of Hml^{P2A} >GFP (attP40), srp^{Hemo} >mCherry animals (top) and surviving Hml^{P2A} >rpr (attP40), srp^{Hemo} >mCherry animals. Hml^{P2A} >rpr (attP40), srp^{Hemo} >mCherry animals still contained srp^{Hemo} >mCherry and showed a wing inflation phenotype.
- (E) Pupal phenotypes of $Hml^{P2A} > rpr$ (attP2) animals. In early pupae (12h after pupariation formation) defective retraction of mouth hooks (white arrowhead) and lack of clearly visible anterior spiracles (yellow arrowhead) is evident. By 24 h after pupariation formation 95% of pupae show a large posterior air bubble (red arrowhead).

(F) Larval survival from controlled density cultures under conventional conditions. Survival was scored as pupae obtained from inoculated 1st instar larvae. Genotypes used here are identical with those in Figure 3F. One-way ANOVA were performed. Controls: attP2>*rpr* and attP2>Bax (A), attP2>Bax (B), yw>*rpr* (C & E), attP2>*rpr* (F).

* p<0.03; ** p<0.002; *** p<0.0002; **** p<0.0001

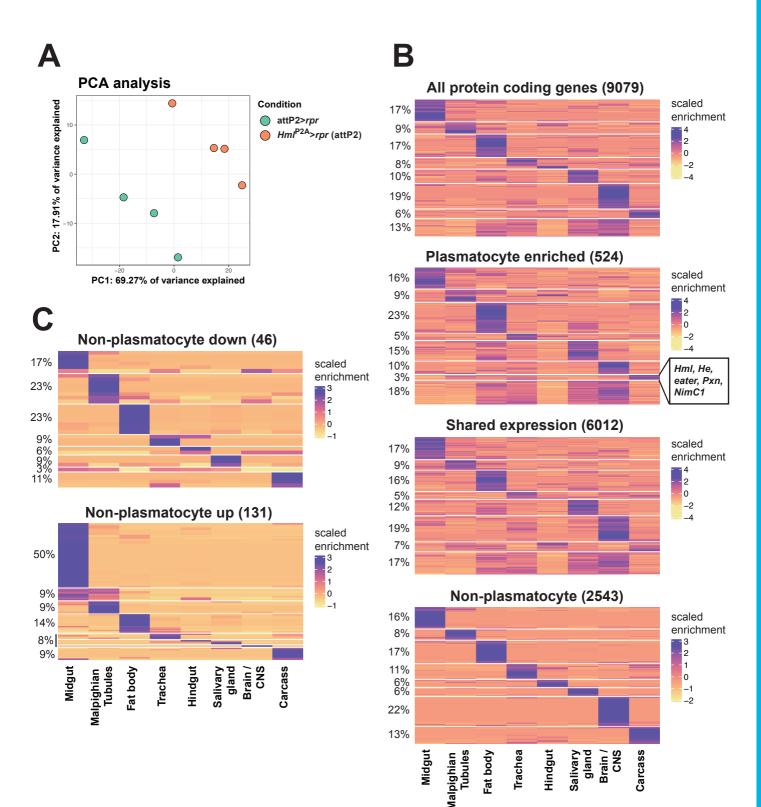

Fig. S5.

- (A) Principle component analysis (PCA) of RNAseq replicate data from $Hml^{P2A} > rpr$ and attP2 > rpr 3rd instar WS larvae. Samples of both genotypes are separated by a shared component in PC1 and PC2, suggesting a consistent transcriptional effect between replicates.
- (B) Heatmap showing scaled tissue enrichment of all protein coding transcripts detected in our differential expression analysis for which data was available at FlyAtlas2 (All protein coding genes) and for subsets identified by our RNAseq analysis as plasmatocyte-enriched, shared or non-plasmatocyte expressed with the number of transcripts in brackets. Known plasmatocyte specific transcripts, which are part of the plasmatocyte enriched subset, show tissue enrichment in the carcass. The percentage of transcripts that are in each k means cluster of the heatmaps is indicated to the left.
- (C) Heatmap showing scaled tissue enrichment of protein coding transcripts that were downregulated and classified as non-plasmatocyte expressed (upper panel) or upregulated and classified as non-plasmatocyte expressed (lower panel). Transcript numbers are indicated by brackets and the percentage of transcripts that are in each k means cluster of the heatmaps is indicated to the left.

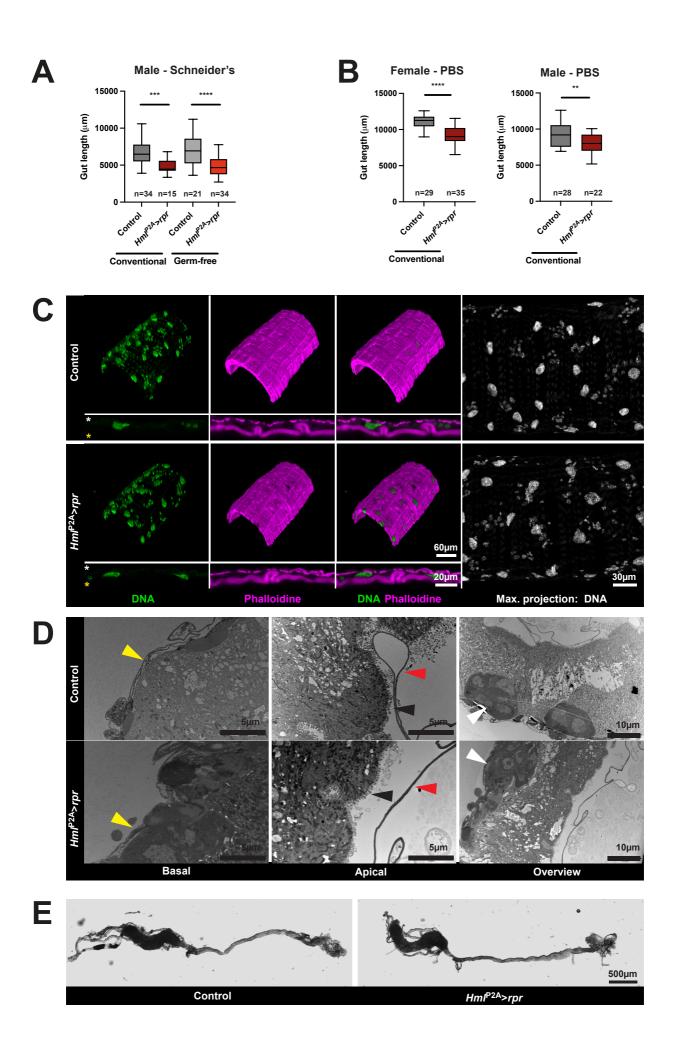

Fig. S6.

- (A & B) Midgut lengths from 3rd instar WS larvae reared at controlled density were determined as outlined in Figure 4D. Dissection was carried out in Schneider's medium containing Ca²⁺ (A) or in calcium-free PBS (B), which reduced the contraction of guts after dissection. In both conditions, *Hml*^{P2A}>*rpr* (attP2) animals showed reduced midgut length compared to controls. This effect was observed despite the sexual dimorphism of midgut length in males and females and under conventional as well as germfree conditions. Number of guts are indicated. One-way ANOVA were performed.
- (C). Fluorescent micrographs of midgut regions close to the midgut/hindgut border from $Hml^{P2A} > rpr$ (attP2) and Control 3rd instar WS larvae reared at controlled density under conventional conditions and dissected in PBS. 3D reconstruction of DNA and Phalloidine staining consistently showed a slight deterioration of visceral musculature. In optical cross sections we observed no difference in staining the musculature on the basal side (white asterisk) and the brush border on the apical side of gut cells (yellow asterisk). Maximum projection of stacks visualized in 3D showed that enterocytes (large nuclei) and smaller cells that might include intestinal stem cells, enteroblasts and enterendocrine cells were present with no apparent differences.
- (D) Electron micrographs of cross sections from the anterior midgut region from $Hml^{P2A} > rpr$ (attP2) and Control 3rd instar WS larvae reared at controlled density under germ-free conditions. Basement membrane (yellow arrowheads), peritrophic membrane (red arrowheads), microvilli (black arrowheads) and longitudinal muscle (white arrowheads) are comparable between the genotypes.
- (E) Brightfield images of pupal guts dissected from $Hml^{P2A} > rpr$ (attP2) 24 h after pupariation and control pupae at 12h after pupariation.

Controls: yw>rpr (A-E). * p<0.03; ** p<0.002; *** p<0.0002; **** p<0.0001

Table S1. RNAseq data from HmlP2A>rpr (attP2) compared to attP2>rpr WS-larvae. Genes were classified as non-plasmatocyte (no or marginal expression in plasmatocytes), shared or plasmatocyte-enriched (>4 fold elevated in plasmatocytes).
