Tetraspanin CD151 and integrin $\alpha 3\beta 1$ contribute to the stabilization of integrin $\alpha 6\beta 4$ -containing cell-matrix adhesions

Lisa te Molder, Juri Juksar*, Rolf Harkes, Wei Wang, Maaïke Kreft and Arnoud Sonnenberg[‡]

ABSTRACT

Tetraspanin CD151 has been suggested to regulate cell adhesion through its association with laminin-binding integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$; however, its precise function in keratinocyte adhesion remains elusive. In this study, we investigated the role of CD151 in the formation and maintenance of laminin-associated adhesions. We show that CD151, through binding to integrin $\alpha 3\beta 1$, plays a critical role in the stabilization of an adhesion structure with a distinct molecular composition of hemidesmosomes with tetraspanin features. These hybrid cell-matrix adhesions, which are formed early during cell adhesion and spreading and at later stages of cell spreading, are present in the central region of the cells. They contain the CD151– $\alpha 3\beta 1/\alpha 6\beta 4$ integrin complexes and the cytoskeletal linker protein plectin, but are not anchored to the keratin filaments. In contrast, hemidesmosomes, keratin filament-associated adhesions that contain integrin $\alpha 6\beta 4$, plectin, BP180 (encoded by *COL17A1*) and BP230 (encoded by *DST*), do not require CD151 for their formation or maintenance. These findings provide new insights into the dynamic and complex regulation of adhesion structures in keratinocytes and the pathogenic mechanisms underlying skin blistering diseases caused by mutations in the gene for CD151.

KEY WORDS: Hemidesmosome, Tetraspanin, CD151, Integrin, Plectin, Keratinocyte adhesion

INTRODUCTION

The skin is our largest organ and its barrier function protects us from dehydration and pathogenic infections. To exert these functions, the skin needs to maintain its integrity, for which stable adhesion of basal keratinocytes to the underlying extracellular basal lamina is of paramount importance. This adhesion is largely mediated by hemidesmosomes (HDs), multi-protein complexes that are associated with the keratin intermediate filament system within the cell.

The integrin $\alpha 6\beta 4$, a heterodimeric transmembrane protein, is a main component of HDs. In type I HDs, present in the epidermis, integrin $\alpha 6\beta 4$ binds extracellularly to laminin-332 and intracellularly via two associated proteins, plectin and BP230 (BPAG1e, encoded by *DST*), to the keratin cytoskeleton. Besides integrin $\alpha 6\beta 4$, type I HDs contain two other transmembrane proteins: the tetraspanin CD151 and BP180 (BPAG2 or collagen XVII, encoded by *COL17A1*) (Litjens et al., 2006; Sterk et al., 2000;

Walko et al., 2015). In more simple epithelia of the intestine or the mammary gland, a rudimentary form of HDs is present. These type II HDs contain integrin $\alpha 6\beta 4$ and plectin, but lack BP180 and BP230 (Fontao et al., 1997; Uematsu et al., 1994).

In humans, the importance of type I HDs for maintaining skin integrity is underscored by genetic evidence that demonstrates that mutations in any of the six genes encoding HD proteins cause the congenital inherited skin blistering disorder epidermolysis bullosa (EB) (Has and Fischer, 2018). Patients carrying null mutations in the genes for the integrin $\alpha 6$ or $\beta 4$ subunits, or the cytolinker protein plectin, suffer from a severe form of EB, which is indicated by the absence of HDs (Ashton et al., 2001; McLean et al., 1996; Nakamura et al., 2005; Niessen et al., 1996; Vidal et al., 1995). However, HDs with grossly normal HD structures, but reduced keratin filament association, are found in patients carrying mutations in the genes for BP180 or BP230, and accordingly, these patients only suffer from a mild form of EB (Groves et al., 2010; Jonkman et al., 1995; Liu et al., 2012; McMillan et al., 1998). Mutations in CD151 have not been associated with abnormalities in HDs but nevertheless cause a mild regional skin blistering phenotype, similar to that observed in patients with mutations in the gene encoding integrin $\alpha 3$ (Crew et al., 2004; Has et al., 2012; Kagan et al., 1988; Vahidnezhad et al., 2017). Targeted deletion of genes encoding HDs and associated proteins in mice largely recapitulates the pathology observed in humans (Andrä et al., 1997; DiPersio et al., 1997; Dowling et al., 1996; Guo et al., 1995; Sachs et al., 2006; van der Neut et al., 1996; Wright et al., 2004).

Integrin $\alpha 3\beta 1$, another laminin-binding integrin expressed by keratinocytes, is a component of focal adhesions (FAs), but can also be found together with integrin $\alpha 6\beta 4$ in tetraspanin-enriched microdomains (TEMs) (also named tetraspanin webs). TEMs are formed by lateral associations of tetraspanins with one another and with other proteins. Incorporation of integrins $\alpha 6\beta 4$ and $\alpha 3\beta 1$ in TEMs is facilitated through binding of their α subunits to CD151 (Hemler, 2005). The association of CD151 with laminin-binding integrins has been reported to affect integrin-dependent adhesion, migration and signaling (Berditchevski, 2001; Stipp, 2010; Termini and Gillette, 2017).

While it has been shown that CD151 is colocalized with integrin $\alpha 6\beta 4$ in type I HDs, the exact function of CD151 in the formation of these adhesions or other cell-matrix adhesions in keratinocytes is not known (Sterk et al., 2002). In this study, we assessed the contribution of CD151 to the formation and maintenance of laminin-associated adhesion complexes in keratinocytes. In agreement with data obtained from CD151 knockout mice and patients with *CD151* mutations, our findings confirm that CD151 is not critical for the formation of type I HDs. However, we show that CD151 is essential for the maintenance of adhesion complexes in which CD151 is present together with integrin $\alpha 3\beta 1$ and the HD proteins integrin $\alpha 6\beta 4$ and plectin, but which are not associated with the keratin cytoskeleton.

RESULTS

CD151 forms multi-protein complexes with both integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ in keratinocytes

Previous studies have shown that CD151 forms stable complexes with the laminin-binding integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ (Hemler, 2005; Sterk et al., 2002). We confirmed these findings by reciprocal co-immunoprecipitation (co-IP) assays using two different monoclonal antibodies against CD151 (5C11 and 11G5) and antibodies against the integrin $\alpha 3$ and $\alpha 6$ subunits (Fig. 1A). Furthermore, these assays showed that in PA-JEB/ $\beta 4$ keratinocytes (immortalized keratinocytes isolated from a patient with pyloric atresia associated with junctional epidermolysis bullosa, and stably expressing wild-type integrin $\beta 4$) the $\alpha 6$ subunit does not form a heterodimer with $\beta 1$, which is consistent with the fact that integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$, but not $\alpha 6\beta 1$, are the major laminin-binding integrins in skin

(Sonnenberg et al., 1991) (Fig. 1A). Using immunofluorescence (IF) microscopy, we detected CD151 in a pattern of consecutive arches, in which it is partially co-localized with integrin $\alpha 3\beta 1$. Both integrin $\alpha 3\beta 1$ and CD151 are also found at the cell periphery where they do not colocalize and are present in distinctive adhesion structures (Fig. 1B). Furthermore, both integrin $\alpha 3\beta 1$ and CD151 co-localized with the HD proteins integrin $\alpha 6\beta 4$ and plectin (Fig. 1C,D). In summary, these results confirm that in keratinocytes CD151 binds both integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$, and is present in adhesion structures that contain characteristics of HDs.

CD151 regulates integrin $\alpha 6\beta 4$ distribution

To determine to what extent CD151 impacts integrin $\alpha 3\beta 1$ - and $\alpha 6\beta 4$ -containing adhesion complexes, we abrogated CD151 protein expression in PA-JEB/ $\beta 4$ and HaCaT keratinocytes using CRISPR-

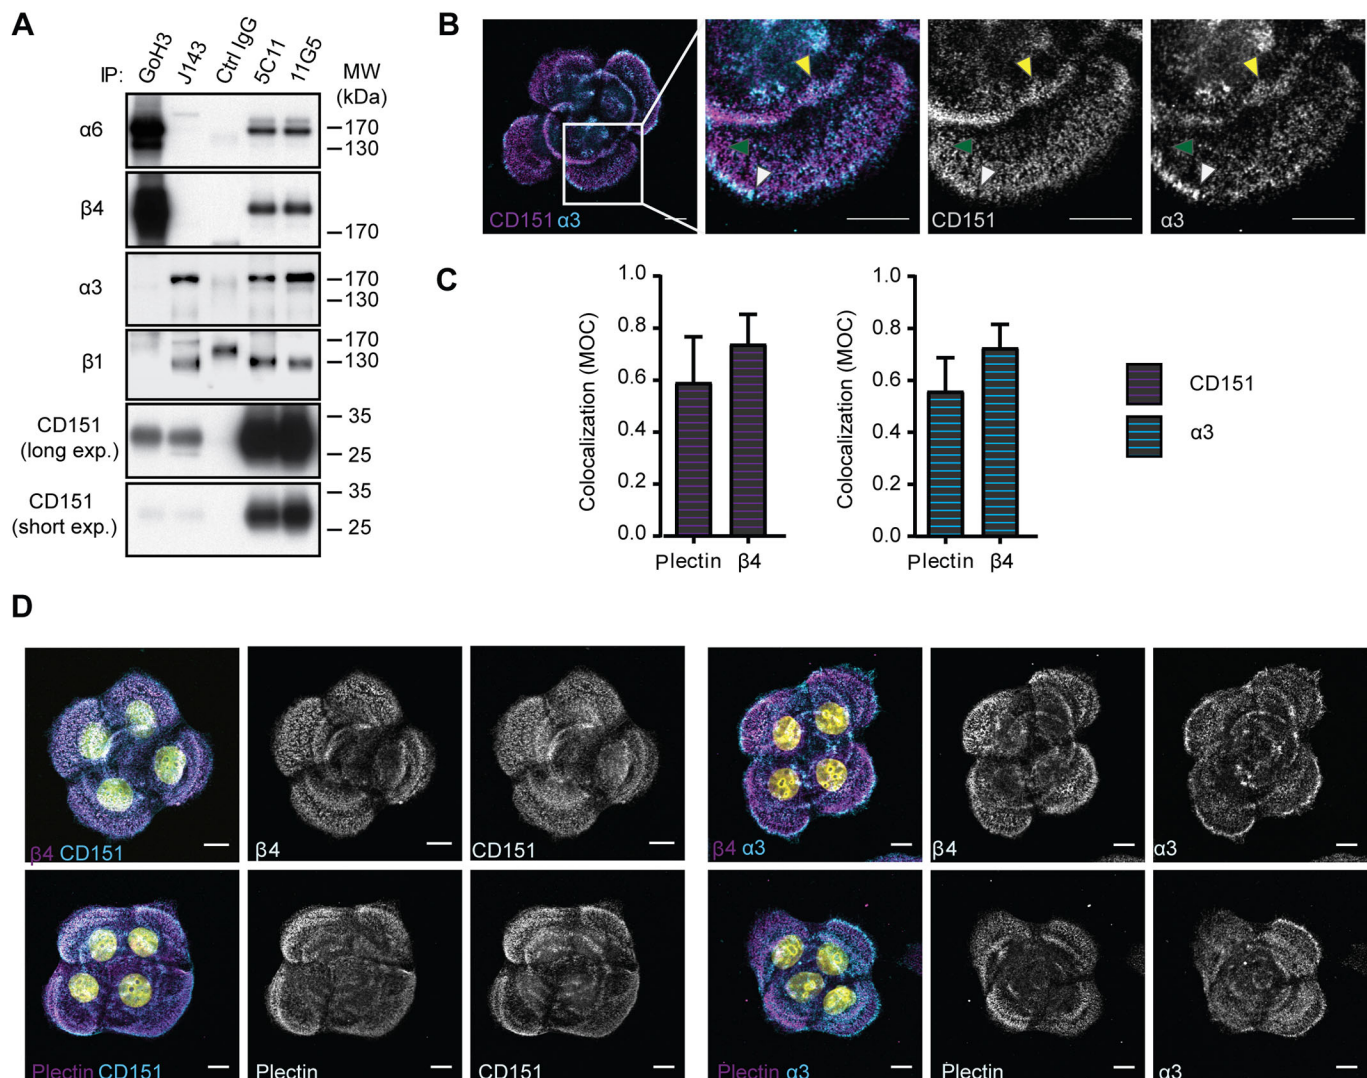

Fig. 1. Association of CD151 with integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ in adhesion complexes. (A) Detection of integrin $\alpha 3\beta 1$ -CD151 and integrin $\alpha 6\beta 4$ -CD151 complexes in lysates of PA-JEB/ $\beta 4$ keratinocytes using immunoprecipitation and western blotting under non-reducing conditions. Antibodies raised against the following proteins were used for immunoprecipitation: GoH3 against integrin $\alpha 6$, J143 against integrin $\alpha 3$, and 5C11 and 11G5 against CD151. (B) Confocal overview and zoom-in image of PA-JEB/ $\beta 4$ cells stained for integrin $\alpha 3$ (cyan) and CD151 (magenta). Yellow arrowheads indicate adhesions containing integrin $\alpha 3$ and CD151 and white and green arrowheads indicate integrin $\alpha 3$ and CD151 located independently of each other in the periphery of the cells. Scale bars: 10 μ m. (C) Quantification (mean \pm s.d.) of the colocalization (Manders' overlap coefficient, MOC) of integrin $\alpha 3$ [46 images from two independent experiments ($N=2$)] or CD151 (30 images; $N=2$) with plectin and integrin $\alpha 3$ (52 images; $N=2$) or CD151 (74 images; $N=4$) with integrin $\beta 4$. (D) Confocal images of double-IF staining of CD151, integrin $\alpha 3$ (cyan) and HD components plectin and integrin $\beta 4$ (magenta) in PA-JEB/ $\beta 4$ keratinocytes. Nuclei were counterstained with DAPI (yellow). Scale bars: 10 μ m.

Cas9 (KO) and subsequently restored the expression of CD151 by retroviral-mediated gene transfer. Analysis by western blotting (WB) and fluorescence-activated cell sorting (FACS) confirmed the absence and restoration of CD151 expression, and showed that the deletion of CD151 did not affect the expression of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ at the plasma membrane (Fig. 2A,B). However, quantitative IF staining and confocal microscopy showed reduced clustering of integrin $\alpha 3\beta 1$ (and to a lesser extent of integrin $\alpha 6\beta 4$) at the basal cell surface (Fig. 2C). Furthermore, integrin $\alpha 3\beta 1$ was no longer co-distributed with integrin $\alpha 6\beta 4$ but showed increased co-localization with phospho-paxillin in FAs (Fig. 2D,E). In the CD151-proficient cells, integrin $\alpha 6\beta 4$ was clustered in central and peripheral adhesions, but strikingly in the CD151-deficient cells it was almost exclusively present at the cell periphery (Fig. 2F–H). These results show that, while not essential for integrin $\alpha 3\beta 1$ or $\alpha 6\beta 4$ protein expression or their transport to the plasma membrane, CD151 is necessary for proper organization of these integrins in the central region of the cells.

CD151 is essential for the maintenance of central integrin $\alpha 6\beta 4$ -containing adhesions

To gain real-time insight into how CD151 contributes to the formation of integrin $\alpha 6\beta 4$ -containing adhesions in the central region of the cells, we deleted CD151 in PA-JEB keratinocytes expressing GFP-tagged integrin subunit $\beta 4$ (Geuijen and Sonnenberg, 2002). The absence of CD151 and presence of $\beta 4$ -GFP was confirmed by FACS and WB analysis (Fig. 3A,B). The clustering of $\beta 4$ -GFP was followed over time in these cells by time-lapse imaging. During initial stages of cell spreading, both CD151-deficient and -proficient PA-JEB/ $\beta 4$ -GFP cells assembled integrin $\alpha 6\beta 4$ -containing adhesions at the periphery of the keratinocyte islands. However, while these initial adhesion structures were maintained during later phases of cell spreading and island formation in the CD151-proficient cells, in the CD151-deficient cells, the central adhesion structures resolved and disappeared when the cells formed new peripheral adhesions after cell division and cell spreading (Fig. 3C; Movies 1 and 2). Furthermore, in fluorescence recovery after photobleaching (FRAP) experiments, a spot in the central and peripheral integrin $\alpha 6\beta 4$ -containing adhesions was simultaneously bleached and the recovery of the $\beta 4$ -GFP signal at these spots was followed over time (Fig. 3D,E). The results show that the mobile fraction of integrin $\alpha 6\beta 4$ in the central integrin $\alpha 6\beta 4$ adhesions is larger than in the peripheral ones, indicating a higher dynamic nature of integrin $\alpha 6\beta 4$ in the central adhesions (Fig. 3E,F).

Peripheral but not central integrin $\alpha 6\beta 4$ -adhesions contain BP230 and are associated with keratin

We reasoned that the observed differences in the dynamics of integrin $\alpha 6\beta 4$ between central and peripheral adhesion clusters could be due to the association of integrin $\alpha 6\beta 4$ with different proteins. Analysis of the distribution of laminin-332 and plectin by total internal reflection fluorescence (TIRF) microscopy showed that both proteins are associated with central and peripheral integrin $\alpha 6\beta 4$ -containing adhesions, with laminin-332 being slightly more abundant under the central adhesion clusters and plectin at the peripheral adhesion clusters (Fig. 4A,B). Strikingly, keratin and BP230 (which, like plectin, can connect integrin $\alpha 6\beta 4$ to the keratin cytoskeleton) were associated solely with integrin $\alpha 6\beta 4$ in the peripheral adhesions (Fig. 4A,B). Interestingly, in the peripheral adhesions only approximately 30 and 50 percent of integrin $\alpha 6\beta 4$ was found to be associated with BP230 and keratin, respectively (Fig. 4B). The possibility that the peripheral adhesions lacking keratin and BP230 are associated with the IF protein vimentin can

be largely excluded since few PA-JEB/ $\beta 4$ keratinocytes express vimentin and even fewer cells have it associated with peripheral adhesions. For similar reasons, we can exclude that the central adhesions are associated with vimentin (Fig. S1). F-actin, which in many PA-JEB/ $\beta 4$ keratinocytes is organized in a typical circumferential ring, was not obviously associated with either the central or peripheral adhesions (Fig. S1). These results characterize many of the peripheral but not the central integrin $\alpha 6\beta 4$ -containing adhesions as type I HDs. Consistent with the notion that type I HDs are present in CD151-deficient patients and mice, the HD proteins BP180, BP230 and plectin were all found to co-localize with integrin $\alpha 6\beta 4$ in the peripheral adhesions of CD151-deficient PA-JEB/ $\beta 4$ keratinocytes (Fig. S2). The central integrin $\alpha 6\beta 4$ -containing adhesion clusters, which share some of the characteristics of HDs, such as the clustering of integrin $\alpha 6\beta 4$ and its association with laminin-332 and plectin, also have features in common with TEMs: they contain integrin $\alpha 3\beta 1$ and CD151 and therefore display a hybrid molecular composition. From this point forward, we will refer to these adhesions as central HD-like adhesions in this report.

Integrin $\alpha 3\beta 1$ is localized in central HD-like adhesions but not in peripheral HDs

Despite the fact that CD151 can form stable complex with both integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$, type I HDs in the skin contain only complexes of CD151 with integrin $\alpha 6\beta 4$ (Sterk et al., 2002; Underwood et al., 2009). To investigate the distribution of integrin $\alpha 3\beta 1$ in relation to CD151 in the different cell-matrix adhesions in the cultured keratinocytes, we performed TIRF imaging and created intensity profiles along a line segment. As shown in Fig. 4, the intensity plots of CD151 and integrin $\alpha 6\beta 4$ in the central HD-like adhesions and the peripheral HDs almost completely overlapped each other (Fig. 4C). In contrast, the profiles of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ only overlapped in the central HD-like adhesions (Fig. 4C). In the peripheral region the peak intensities of integrin $\alpha 3\beta 1$ overlapped with those of tyrosine phosphorylated FA-associated protein paxillin, and not with HD markers BP230 and keratin (Fig. 4D). These results confirm that central and peripheral adhesions differ in protein composition. Furthermore, while in the central HD-like adhesions integrin $\alpha 3\beta 1$, integrin $\alpha 6\beta 4$ and CD151 cluster together, in the periphery they can be found in two distinct complexes: integrin $\alpha 3\beta 1$ in FAs and integrin $\alpha 6\beta 4$ and CD151 in type I HDs.

CD151 stabilizes central HD-like adhesions through binding to integrin $\alpha 3\beta 1$ and self-association

Our findings so far indicate that CD151 is essential for maintaining central HD-like adhesions. To determine whether CD151 stabilizes these adhesions through binding to integrin $\alpha 3\beta 1$, we deleted and reconstituted integrin $\alpha 3$ in the HaCaT and PA-JEB/ $\beta 4$ keratinocyte cell lines (Fig. 5A,B; Fig. S3A,B). In both these cell lines, the absence of integrin $\alpha 3$ did not affect the total levels of integrin $\beta 4$ at the cell surface and the formation of peripheral HDs was not obviously disturbed. However, as observed in the CD151-deficient PA-JEB/ $\beta 4$ keratinocytes, the absence of integrin $\alpha 3$ caused a loss of central HD-like adhesions, albeit less dramatically (Fig. 5B–D; Fig. S3C). To exclude the possibility that the absence of the central HD-like adhesions is caused by reduced spreading of the integrin $\alpha 3$ -deficient cells, we also analyzed the cells that were plated on coverslips coated with a mixture of vitronectin and fibronectin. Under these conditions, cell spreading of the integrin $\alpha 3$ -deficient cells was increased and found to be comparable to that of the wild-

(G) Quantification (mean \pm s.d.) of the amount of central integrin $\alpha 6\beta 4$ -containing adhesions per cell island (dots represent individual cell islands) using images from WT (57 images; $N=4$), CD151-KO (56 images; $N=4$) and CD151-RESC (55 images; $N=4$) PA-JEB/ $\beta 4$ cells stained for integrin $\beta 4$. **** $P<0.0001$ (Mann–Whitney U -test). (H) Scoring system for the amount of central integrin $\alpha 6\beta 4$ -containing adhesions present, with example images. 0=no central adhesion, 1=few central adhesions, 2=several central adhesions, 3=many central adhesions. Scale bars: 10 μ m.

type cells on uncoated coverslips. Importantly, the difference in the amount of central HD-like adhesions persisted between the integrin $\alpha 3$ -deficient and -proficient cells (Fig. S3D,E).

Next, we investigated whether the role of integrin $\alpha 3\beta 1$ in maintaining the central HD-like adhesions requires binding of integrin $\alpha 3\beta 1$ to laminin-332. To this end, we introduced a binding-deficient integrin $\alpha 3$ mutant (G163A) into integrin $\alpha 3$ -deficient HaCaT cells (Zhang et al., 1999). Expression of the mutant integrin $\alpha 3\beta 1$ was verified by FACS analysis (Fig. 5B). Unlike the wild-type integrin $\alpha 3$ subunit, the integrin $\alpha 3$ -G163A mutant was unable to completely rescue the central HD-like adhesions, suggesting that integrin $\alpha 3\beta 1$ binding to laminin contributes to efficient maintenance of these adhesions (Fig. 5C,D). These findings were confirmed in PA-JEB/ $\beta 4$ cells using the integrin $\alpha 3$ blocking antibody, J143 (Fig. S3F,G).

Palmitoylation of CD151 is necessary for stabilization of the CD151 TEMs and hence for incorporation and clustering of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ into these multi-molecular complexes of CD151 (Berditchevski et al., 2002; Yang et al., 2002). To study the role of this self-associating function of CD151 for stabilization of the central HD-like adhesions, we introduced a CD151 palmitoylation mutant into the CD151-deficient PA-JEB/ $\beta 4$ keratinocytes (Fig. 5B) (Berditchevski et al., 2002). The expression of this mutant in CD151 KO cells did not rescue the central HD-like adhesions, suggesting that for the maintenance of these clusters CD151 needs to form multi-molecular complexes by oligomerization (Fig. 5E,F; Fig. S3H).

Taken together, these results show that for efficient maintenance of the central HD-like adhesions, both laminin-332-associated integrin $\alpha 3\beta 1$ and self-associated and TEM-forming CD151 are needed.

Laminin-332, but not plectin, contributes to clustering of integrin $\alpha 6\beta 4$ in central HD-like adhesions

Since the peripheral HDs and central HD-like adhesions contain more plectin and laminin, respectively, we studied whether CD151-mediated clustering of integrin $\alpha 6\beta 4$ in the different adhesions requires binding of integrin $\alpha 6\beta 4$ to laminin-332 or plectin.

Therefore, we expressed the integrin $\beta 4$ mutants, $\beta 4$ -AD and $\beta 4$ -RW, in integrin $\beta 4$ -deficient PA-JEB keratinocytes (Fig. 6A). The $\beta 4$ -AD mutant is an adhesion-defective mutant that cannot bind to laminin-332, while the $\beta 4$ -RW mutant, carrying a single missense mutation R1281W in the cytoplasmic domain of integrin $\beta 4$, is unable to bind plectin (Geerts et al., 1999; Nievers et al., 2000; Russell et al., 2003). In the $\beta 4$ -AD mutant-expressing cells, central HD-like adhesions were less commonly present than in the wild-type integrin $\beta 4$ ($\beta 4$ -WT)-expressing cells (Fig. 6B,C). Similar findings were obtained when PA-JEB/ $\beta 4$ and HaCaT cells were treated with the integrin $\beta 4$ blocking antibody ASC8 (Russell et al., 2003). In the presence of this blocking antibody, the central HD-like adhesions are mostly absent, while there are abundant peripheral HDs (Fig. 6D,E). In the cells expressing the $\beta 4$ -RW mutant and in plectin-deficient PA-JEB/ $\beta 4$ keratinocytes, the integrin $\alpha 6\beta 4$ staining was diffused and adhesions were less well-defined. Nevertheless, in many cell islands some central HD-like adhesions could be observed (Fig. 6B,C,F,H). In addition, the loss of plectin resulted in a reduction of peripheral HDs (Fig. 6G,H). These results indicate that the binding of integrin $\alpha 6\beta 4$ to laminin-332, as for integrin $\alpha 3\beta 1$, contributes to the stabilization of the central HD-like adhesions. By contrast, binding of integrin $\alpha 6\beta 4$ to plectin is not essential, but might contribute to the clustering of this integrin in the peripheral type I HDs.

CD151 does not affect the strength of integrin $\alpha 6\beta 4$ -mediated cell adhesion

Integrin clustering determines the strength with which cells adhere to the extracellular matrix (ECM) (Puklin-Faucher and Sheetz, 2009). To investigate whether CD151-mediated clustering of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ strengthens the adhesion of keratinocytes to laminin-332 deposited by the cells to the substratum, we quantified the adhesion strength of CD151-proficient and -deficient HaCaT keratinocytes, which express both integrin $\alpha 3\beta 1$ and $\alpha 6\beta 4$, using a spinning disk device (Boettiger, 2007). CD151-deficient cells showed a reduced tolerance (albeit not statistically significant) of shear stress compared to the CD151-proficient cells (Fig. 7A), suggesting that CD151 plays only a minor role in adhesion strengthening when both integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ are present. Next, we investigated whether cell adhesion mediated by either integrin $\alpha 3\beta 1$ or $\alpha 6\beta 4$ is strengthened by CD151. To resolve this, we individually deleted integrin $\alpha 3$ and integrin $\beta 4$ in the CD151-deficient HaCaT keratinocytes and confirmed the absence of these proteins by FACS and WB analysis (Fig. 7B,C). The deletion of integrin $\alpha 3$ in the CD151-deficient HaCaT keratinocytes had no effect on the adhesive strength of integrin $\alpha 6\beta 4$ to laminin-332 (Fig. 7D). However, in the absence of integrin $\alpha 6\beta 4$, the additional loss of CD151 resulted in a significant reduction in integrin $\alpha 3\beta 1$ -mediated adhesion strengthening (Fig. 7E,F). We conclude that CD151 significantly strengthens integrin $\alpha 3\beta 1$ -, but not integrin $\alpha 6\beta 4$ -mediated cell adhesion by facilitating the clustering of this integrin into central HD-like adhesions.

DISCUSSION

CD151 has been shown to be broadly expressed by a variety of cell types and to form complexes with different laminin-binding integrins, including integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ (Sincock et al., 1997). In skin, CD151 is complexed with integrin $\alpha 6\beta 4$ and is a component of HDs (Sterk et al., 2000). In this study, we show that in cultured keratinocytes CD151 is not only present in HDs, but also in an adhesion structure with a distinct molecular composition of a HD with tetraspanin features. These hybrid adhesion structures, which are present in the central region of the cell, and referred to as central

(C) Stills from a time-lapse experiment using WT and CD151-KO PA-JEB/ $\beta 4$ -GFP cells. Top panels show the integrin $\beta 4$ -GFP signal and bottom panels the overlay of the integrin $\beta 4$ -GFP and DIC signal. Stills show images taken at 1, 4, 8, 12, 16 and 20 h after addition of DMEM+FCS (0 h time point, 20 h after seeding). The yellow arrowheads indicate a peripheral adhesion becoming a central adhesion over time in WT cells and the blue arrowheads indicate a peripheral adhesion disappearing over time in KO cells. Scale bars: 10 μ m. (D) Example image of PA-JEB/ $\beta 4$ -GFP after the bleach step of a FRAP experiment; FRAP regions indicated in peripheral and central adhesions with yellow circles. Scale bar: 10 μ m. (E) Integrin $\beta 4$ -GFP intensity (relative to the mean integrin $\beta 4$ -GFP intensity before bleaching) over time (in seconds) during FRAP experiments in both central (blue) and peripheral (grey) integrin $\alpha 6\beta 4$ -containing adhesions. Data was collected from 38 islands in three experiments, lineplot shows the mean+s.d. (F) Mobile fraction and recovery time of integrin $\beta 4$ -GFP in central and peripheral adhesions during the first 230 s of the same dataset used for E. Boxplots divide the data in quartiles and the median is indicated. The whiskers show minimal and maximal values. ** $P < 0.01$, *** $P < 0.001$ (Wilcoxon matched-pairs signed rank test) in E,F.

HD-like adhesions, contain the cytolinker plectin in addition to the CD151- $\alpha 3\beta 1/\alpha 6\beta 4$ integrin complexes, but are not associated with keratin filaments. We further show that CD151, through its binding to integrin $\alpha 3\beta 1$, is critical for the formation and stabilization of these central HD-like adhesions and strengthens integrin $\alpha 3\beta 1$ - but not integrin $\alpha 6\beta 4$ -mediated keratinocyte adhesion to laminin-332. CD151 is not needed for the formation of type I HDs that are formed in the periphery of the cells and are anchored to keratin filaments (Fig. 8).

The mechanistic reasons for the lack of association of keratin filaments with the central HD-like adhesions can be surmised based on previous studies. PKA-mediated phosphorylation of plectin at S4642 interferes with its interaction with intermediate filaments (Bouameur et al., 2013), and therefore, it is possible that plectin is phosphorylated at this residue in the central HD-like adhesions, which prevents its association with keratin filaments. Additionally, BP230, which is present in peripheral HDs but not central HD-like adhesions, may be required for efficient attachment of keratin filaments to the plasma membrane. In support of this supposition, BP230 knockout mice showed an impaired connection of keratin filaments with HDs (Guo et al., 1995). Similarly, reduced amounts of keratins are associated with type II HDs, which contain plectin but lack BP230 (Fontao et al., 1997; Uematsu et al., 1994).

Although an essential role of CD151 in the formation of type I HDs was not evident from our current experiments, a more subtle role of CD151 for the formation of HDs cannot be excluded. The ability of CD151 to facilitate the clustering of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ into central HD-like adhesions may strengthen keratinocyte adhesion to newly deposited laminin-332 before FAs and HDs are fully established; however, once integrins are connected to the cytoskeleton, the function of CD151 as a clustering molecule may no longer be required. This model would indicate an important role of CD151-mediated adhesion strengthening and clustering of integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$ into central HD-like adhesions *in vivo*. For example, during re-epithelization of wounded skin, when HDs are dissolved and stable adhesion of the keratinocytes to the basal lamina is no longer assured, the central HD-like adhesions may prevent detachment of migrating keratinocytes that are subject to external mechanical forces. At the same time, they may render the adhesion of keratinocytes sufficiently dynamic to allow integrin

turnover and migration to occur. Consistent with a role of the central HD-like adhesions in migration, we found that these adhesions are more dynamic than the type I HDs.

Despite the fact that the association of BP230 with keratin filaments at type I HDs increases their stability (Michael et al., 2014; Seltmann et al., 2013), our FRAP analyses showed only a modest increase in the stability of the peripheral HD adhesions compared to the central HD-like adhesions. Since our FRAP analyses do not distinguish between peripheral adhesions that are or are not associated with keratin filaments, this apparent discrepancy may be explained by the notion that not all of the peripheral adhesions are associated with keratin filaments. Furthermore, it should be understood that the peripheral type I HDs lack integrin $\alpha 3\beta 1$, whose presence in the HD-like adhesions contributes to their stability.

In central HD-like adhesions, CD151 and integrin $\alpha 3\beta 1$ colocalize, but in the periphery CD151 associates with type I HDs and integrin $\alpha 3\beta 1$ is localized into FAs. The localization of integrin $\alpha 3\beta 1$ into FAs coincides with the incorporation of BP230 in HDs. Since the localization of BP180 in type I HDs precedes that of BP230 (Koster et al., 2003), it is possible that BP180 displaces integrin $\alpha 3\beta 1$ from CD151 and allows the integrin to become incorporated into FAs. In this respect it is interesting to mention that, like CD151 and the integrin $\alpha 3$, $\alpha 6$ and $\beta 4$ subunits (Yang et al., 2004), BP180 contains several cysteine residues adjacent to its transmembrane domain that are potential sites of palmitoylation. The role of protein palmitoylation in the formation of HDs is not known, but it is reasonable to suggest that it might help to increase the local concentration of HD proteins, and facilitate the assembly and stability of HDs.

In agreement with our finding that HDs can be formed in the absence of integrin $\alpha 3\beta 1$ in cultured keratinocytes, no obvious abnormalities in HDs have been observed in mice lacking integrin $\alpha 3$ in basal keratinocytes (Conti et al., 2003; DiPersio et al., 1997; Margadant et al., 2009). Yet, genetic ablation of the $\beta 1$ integrin subunit or its co-activator kindlin-1 (encoded by *FERMT1*) in basal keratinocytes has been associated with reduced HD protein expression and formation of HDs (Brakebusch et al., 2000; Qu et al., 2012; Raghavan et al., 2000). This suggests that if integrin $\alpha 3\beta 1$ has a role in HD formation, this role could be fulfilled by other integrins, as well. Furthermore, our finding that CD151 contributes to integrin $\alpha 3\beta 1$ - but not integrin $\alpha 6\beta 4$ -mediated strengthening of cell adhesions is consistent with the respective roles these proteins play in mediating cell-matrix adhesion in the skin and kidney. In the skin, where basal keratinocytes express both integrins $\alpha 3\beta 1$ and $\alpha 6\beta 4$, the effect of CD151 deletion is relatively mild, and patients display only a mild skin blistering disorder. In contrast, the loss of CD151 in glomerular podocytes, which express integrin $\alpha 3\beta 1$ but not integrin $\alpha 6\beta 4$, has been associated with progressive and irreversible kidney dysfunction (Crew et al., 2004; Kagan et al., 1988; Sachs et al., 2012; Vahidnezhad et al., 2017).

In conclusion, we show that CD151 stabilizes the central HD-like adhesions by strengthening the adhesion of integrin $\alpha 3\beta 1$ to laminin-332 and facilitating the incorporation of integrin $\alpha 6\beta 4$ into TEMs containing integrin $\alpha 3\beta 1$. By contrast, CD151 is not needed for the formation or stabilization of integrin $\alpha 6\beta 4$ -containing type I HDs in the periphery of the cells, which are linked to keratin filaments. These data provide new insights into the role of CD151 in the formation and maintenance of different populations of adhesions that are formed in cultured keratinocytes. Importantly, our study reflects the skin conditions observed in patients and mice with mutations in CD151 and integrin $\alpha 3\beta 1$, and thus provides better understanding of the mechanisms underlying these conditions.

Fig. 4. Central and peripheral adhesions differ in protein composition.

(A) TIRF images of PA-JEB/ β 4 keratinocytes stained for integrin β 4 (magenta) and laminin-332, plectin, keratin-14 or BP230 (cyan). Scale bars: 10 μ m. (B) Quantification of the integrin β 4 area which is positive for laminin-332 (57 images; $N=2$), plectin (60 images; $N=2$), keratin-14 (59 images; $N=2$) or BP230 (61 images; $N=2$) in peripheral and central integrin α 6 β 4-containing adhesions. Boxplots divide the data in quartiles and the median is indicated. The whiskers show the minimal and maximal values. **** $P<0.0001$ (Mann–Whitney U -test). (C,D) TIRF images of PA-JEB/ β 4 cells stained for integrin β 4 (magenta) and CD151 or integrin α 3 (cyan) (C), or integrin α 3 (magenta) and phosphorylated paxillin, BP230 or keratin (cyan) (D). Scale bars are 10 μ m. Line plot shows the relative fluorescence intensities (normalized to the highest pixel intensity) of the different proteins along the line (thickness: 10 pixels) indicated in the overlay image. The line starts in the periphery (P) and is drawn towards the center (C) of the island.

MATERIAL AND METHODS**Antibodies**

The primary and conjugated antibodies used in this study are listed in Table S1. Secondary antibodies for western blotting were goat anti-mouse

IgG HRP (1:3000; Bio-Rad, 170-6516) and polyclonal goat anti-Rabbit IgG HRP (1:5000; Dako, P044801-2). Donkey anti-mouse IgG PE (1:500; Jackson ImmunoResearch, 715-116-150) was the secondary antibody used in FACS. For immunofluorescence (IF), rabbit anti-rat IgG (1:1000; in-house), goat anti-guinea pig IgG Alexa Fluor 488, goat anti-human IgG Alexa Fluor 488, goat anti-mouse Alexa Fluor 568, goat anti-mouse Alexa Fluor 647, goat anti-rabbit Alexa Fluor 488, goat anti-rabbit Alexa Fluor 647, goat anti-rat Alexa Fluor 647 (1:200; Invitrogen, A-11073, A-11013, A-11004, A-21236, A-21245, A-21034, A-21245, A-21247), goat anti-mouse FITC, goat anti-rat FITC (1:200; Rockland, 610-102-121 and 612-102-120) and the isotype-specific goat anti-mouse IgG1 Alexa Fluor 568 (1:500; Thermo Fisher Scientific, A-21124) and goat anti-mouse IgG2a FITC (1:250; Abcam, ab98697) were used secondary antibodies.

Cell lines

PA-JEB immortalized keratinocytes were isolated from a patient with pyloric atresia associated with junctional epidermolysis bullosa (Niessen et al., 1996; Schaapveld et al., 1998). The derivation of this cell line was done for diagnostic purposes, thus, the research conducted using these cells was exempt from the requirement for ethical approval. PA-JEB/ β 4

keratinocytes stably expressing wild-type $\beta 4$ were generated by retroviral transduction (Sterk et al., 2000) and maintained in serum-free keratinocyte medium (KGM; Invitrogen), supplemented with 50 μ g ml $^{-1}$ bovine pituitary gland extract, 5 ng ml $^{-1}$ EGF, and antibiotics (100 units ml $^{-1}$ streptomycin and 100 units ml $^{-1}$ penicillin; Sigma-Aldrich). Human HaCaT keratinocytes were obtained from Dr Fusenig of the German Cancer Center (DKFZ) in Heidelberg, Germany and cultured in Dulbecco's modified Eagle's medium (DMEM; Gibco) containing 10% heat-inactivated fetal calf serum (FCS; Serana) and antibiotics. All cells were cultured at 37°C in a humidified, 5% CO $_2$ atmosphere.

The integrin $\alpha 3$ -, integrin $\beta 4$ -, CD151- and plectin-deficient cells were prepared using CRISPR-Cas9 technology. Target sgRNAs against integrin $\alpha 3$ (5'-GCTACTCGGTCGCCCTCCAT-3'), integrin $\beta 4$ (5'-GACTCGCTCCCTCCGCGCT-3'), CD151 (5'-CAGGTTCCGACGCTCCTTGA-3') and plectin (5'-GAGGTGCTTGTGACCACT-3') were cloned into the pX330-U6-Chimeric_BB-CBh-hSpCas9 (Addgene plasmid #42230, deposited by Feng Zhang). For the integrin $\alpha 3$ -, integrin $\beta 4$ - and CD151-deficient cells, cells were transiently transfected with this plasmid using

Lipofectamine[®] 2000 (Invitrogen) in OptiMEM (Gibco). The cells were bulk sorted for the population deficient of the protein of interest using a Moflo Asterios (Beckman Coulter) or FACSaria Fusion (BD Biosciences) cell sorter. For the preparation of the plectin-deficient cells, cells were co-transfected with a plasmid containing a blasticidin cassette flanked by TIA target sites (described by Blomen et al., 2015), blasticidin-resistant cells were enriched by selection for four days in the presence of blasticidin (4 μ g ml $^{-1}$; Sigma-Aldrich), clones were picked and analyzed for plectin expression by western blotting.

For (re)expression of proteins in protein-deficient cells, we used stable cellular retroviral-mediated transduction. Cells that expressed the protein were enriched by zeocin or blasticidin selection and/or by bulk sorting by FACS. The constructs used were: the $\beta 4$ -AD mutant (D230A, P232A and E233A) in LZRS-IRES-blasticidin, a kind gift from Peter Marinkovich (Russell et al., 2003), the CD151 wild-type and CD151 palmitoylation mutant in LZRS-IRES-Zeo, constructed by introducing the CD151 cDNA released from pZeo-CD151 or pZeo-CD151-PALM [gift from F. Berditchevski (Berditchevski et al., 2002)] and the integrin $\alpha 3$ wild-type

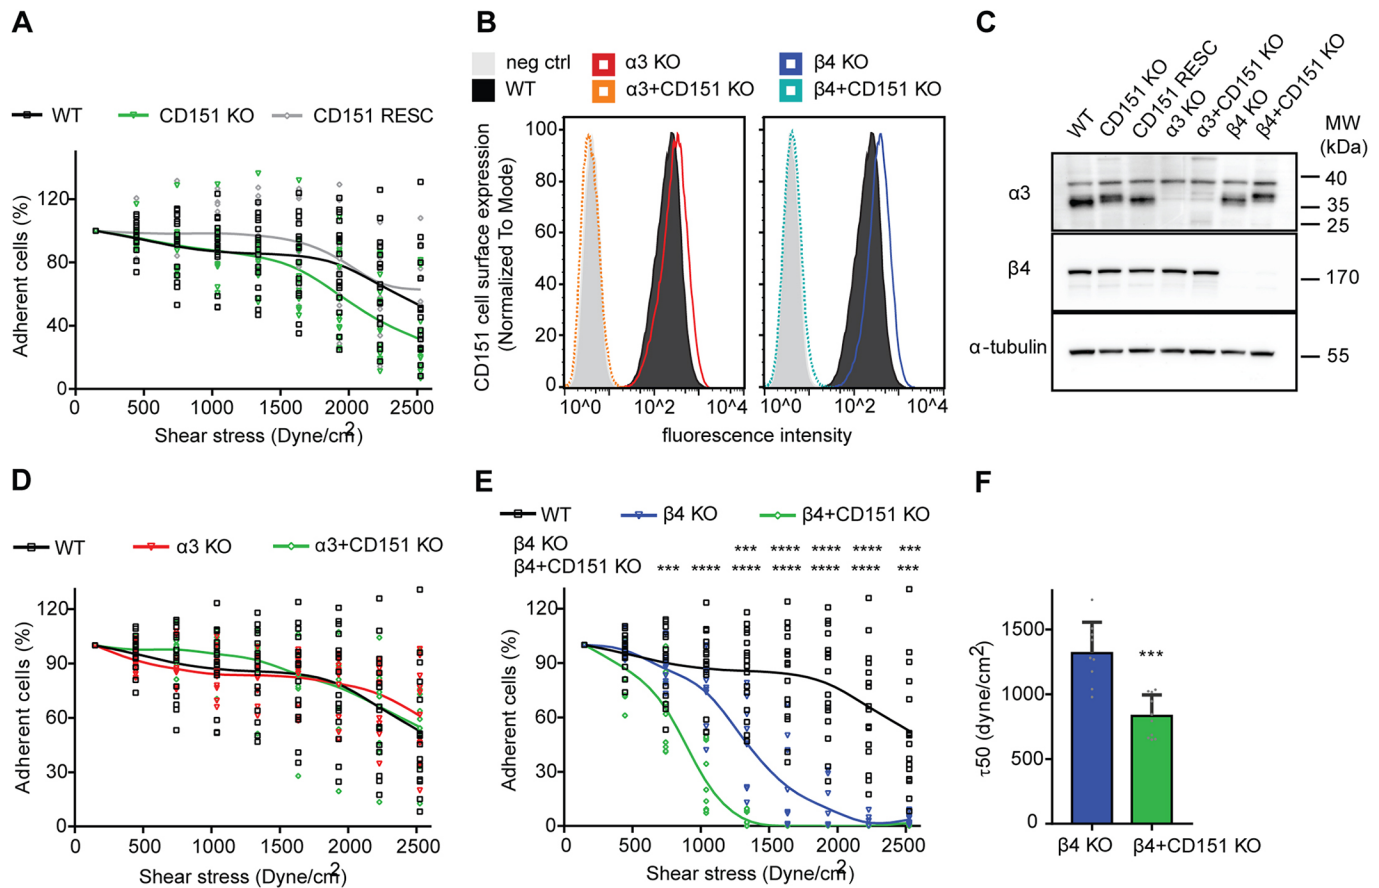

Fig. 7. CD151 contributes to integrin $\alpha 3\beta 1$ -mediated adhesion strengthening. (A) Percentage of WT (squares; $n=16$), CD151-KO (triangles; $n=13$) and CD151-RESC (diamonds; $n=14$) HaCaT keratinocytes that remained adherent under conditions of increasing shear stresses (shown in dynes/cm²). (D,E) Percentage of WT (squares; $n=16$), $\alpha 3$ -KO (triangles; $n=11$) and double $\alpha 3$ +CD151 KO (diamonds; $n=11$) HaCaT keratinocytes (D) and of WT (squares; $n=16$), $\beta 4$ -KO (triangles; $n=9$) and double $\beta 4$ +CD151 KO (diamonds; $n=10$) HaCaT keratinocytes (E) that remained adherent after being submitted to increasing conditions of shear stresses (in dynes/cm²). Line depicts the mean; *** $P<0.001$, **** $P<0.0001$ (unpaired t -tests corrected for multiple comparisons). (F) Mean \pm s.d. $\tau 50$ calculated for $\beta 4$ -KO and double $\beta 4$ +CD151 KO HaCaT cells from the same dataset shown in E. *** $P<0.001$ (Mann–Whitney U -test).

in LZRS-IRES-Zeo. The integrin $\alpha 3$ cDNA has been described previously (Delwel et al., 1994) and the full-length cDNA encoding human integrin $\alpha 3$ was released from pUC18 by digesting with *Sph*I, made blunt by Klenow digestion and ligated into the *Swa*I site of the retroviral LZRS-IRES-zeo vector. Furthermore, the integrin $\alpha 3$ -G163A mutant in pBJ-1 expression vector (Zhang et al., 1999) was a gift from Yoshikazu Takada (University of California, Davis, USA) and transiently transfected in $\alpha 3$ -deficient cells. Generation of PA-JEB keratinocytes stably expressing integrin $\beta 4$ [$\beta 4$ RW (R1281W)] has been described previously (Geerts et al., 1999).

Immunofluorescence imaging of fixed samples

For image acquisition, cells were seeded at ~10–20% confluence onto glass coverslips, uncoated or coated with 10 μ g ml⁻¹ fibronectin from bovine plasma (F1141, Sigma-Aldrich) and 5 μ g ml⁻¹ vitronectin (SRP3186, Sigma-Aldrich) and grown for 40–44 h of which at least the last 20 h in the presence of DMEM+FCS. After the cells had been fixed with 2% PFA for 10 min, permeabilized with 0.2% Triton X-100 and blocked with 2% BSA (resolved in PBS; Serva), they were incubated for 50–60 min with primary and secondary antibodies, with three PBS washes in between. Nuclei were counterstained with DAPI (Sigma-Aldrich) and coverslips were mounted with MOWIOL for confocal imaging. For TIRF imaging, coverslips were stored in PBS at 4°C until imaging.

Confocal imaging was performed using a Leica TCS SP5 confocal microscope with a 63 \times (NA 1.4) oil objective. A Leica SR-GSD microscope (Leica Microsystems, Wetzlar, Germany) equipped with a 160 \times oil immersion objective (NA 1.47) and an EMCCD Andor iXon camera (Andor Technology, Belfast, UK) was used to acquire TIRF images with an imaging depth of 200 nm. To be able to perform subsequent analyses, imaging was performed under consistent conditions.

Image analyses were performed using ImageJ: Co-localization was assessed using Manders' overlap coefficient (MOC) with the JACoP plugin. The amount of basal cell surface clustering was quantified by calculating the integrated density of the staining. The intensity of the integrin $\beta 4$ staining in the peripheral adhesions was obtained by drawing a region of interest around the peripheral adhesions and measuring the mean intensity of the integrin $\beta 4$ staining in this region. The percentage of integrin $\beta 4$ associated with plectin, BP230, keratin 14 or laminin-332 was obtained by calculating how much of the integrin $\beta 4$ -positive area was additionally positive for plectin, BP230, keratin or laminin-332. The quantification of the island sizes was performed by thresholding images based on their staining with Phalloidin-iFluor647 (AAT Bioquest) and measuring the surface area after selecting the outer region. Furthermore, the quantification of the amount of central integrin $\beta 4$ clusters present per cell island was performed using an arbitrary scoring system (0=no central adhesions, 1=few central adhesions, 2=several central adhesions, 3=many central adhesions).

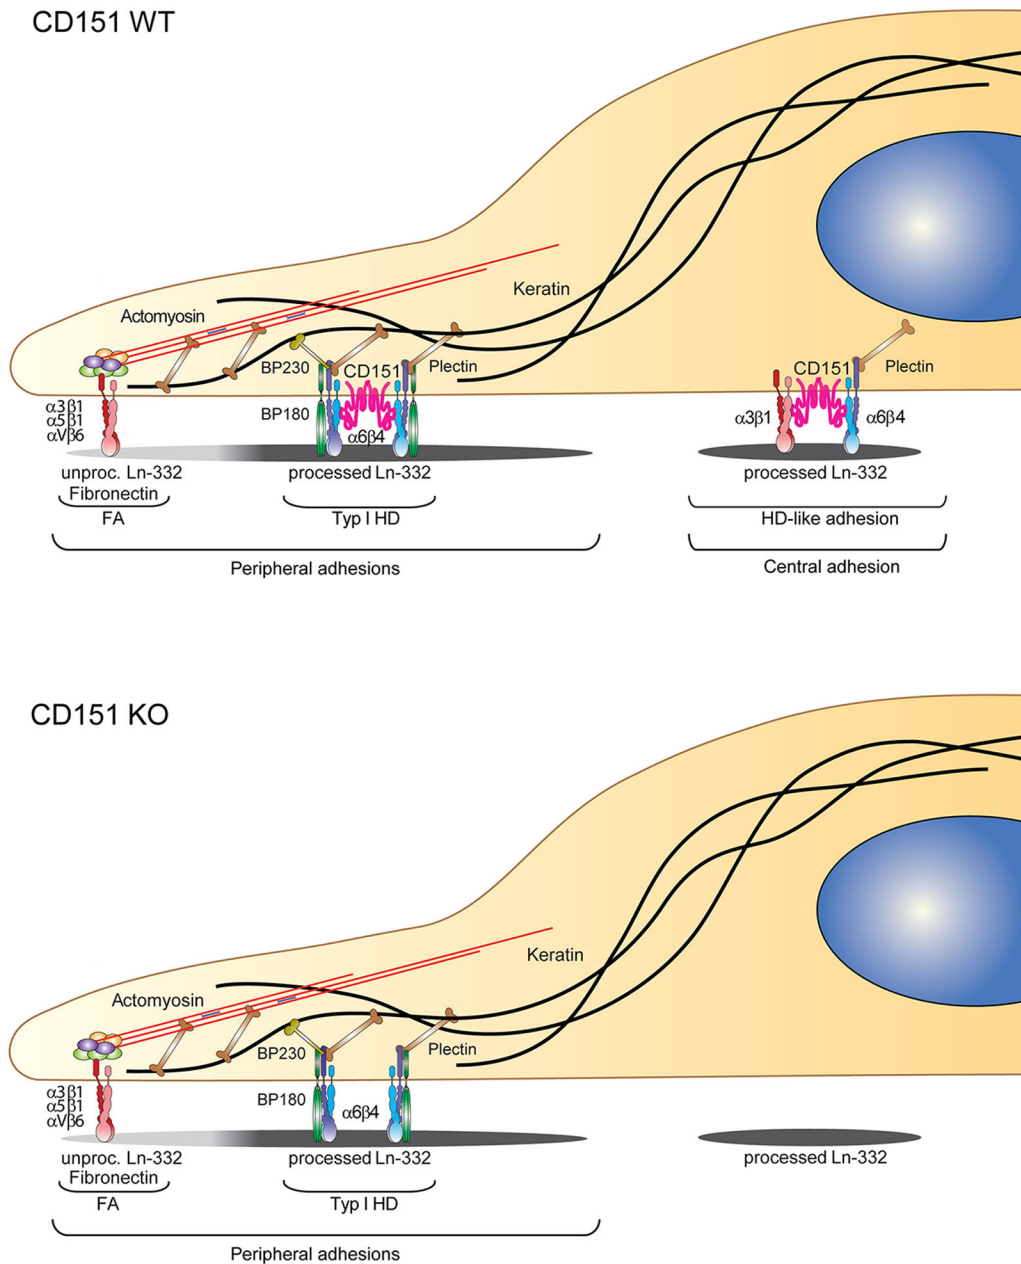

Fig. 8. CD151 is essential for the maintenance of central HD-like adhesions but not the formation of peripheral FAs and type I HDs. In the presence of CD151 (top panel), integrins $\alpha3\beta1$ and $\alpha6\beta4$ are present together with CD151 in central HD-like adhesions. Additionally, integrin $\alpha3\beta1$ is present in FAs in the periphery of the cell island preceding the type I HDs in which integrin $\alpha6\beta4$ is present also together with CD151. In the absence of CD151 (bottom panel), the peripheral adhesions are still formed but lack CD151, while the central HD-like adhesions are lost.

Graphs were made using GraphPad Prism and include bar graphs showing the mean \pm s.d. (including dots that represent independent measurement) or boxplots dividing the data in quartiles. The number of images used for analyses is specified in the figure legends and statistical significance was calculated using the non-parametric and non-paired Mann-Whitney *U*-test; *P*-values: * <0.05 , ** <0.01 , *** <0.001 , **** <0.0001 .

Live imaging and FRAP

For live imaging and fluorescence recovery after photobleaching (FRAP), cells were seeded on 24 mm coverslips and imaging was performed using a Leica TCS SP5 confocal microscope with a $63\times$ (NA 1.4) oil objective equipped with a live cell chamber. Live imaging of CD151-proficient and -deficient PA-JEB/ $\beta4$ -GFP cells was started 20 h after seeding and immediately after replacing the KGM medium with DMEM+FCS. Every hour the differential interference contrast (DIC) and GFP fluorescence signals were collected from multiple cell islands at different positions. Videos were made in ImageJ.

FRAP experiments were performed, using the FRAP wizard in LAS-AF (Leica), using PA-JEB/ $\beta4$ -GFP cells grown for 20 h in KGM medium

and subsequently grown for an additional 20 h in DMEM+FCS. Simultaneously, a region in one peripheral and one central integrin $\alpha6\beta4$ -containing adhesion was bleached and fluorescent recovery was followed over time. Two images as controls were taken before bleaching and then one image every 10 s (first 2 min) or 30 s for 15 min after bleaching. For analyses, the background was subtracted from the measured intensities and the curves were normalized to the mean value before bleaching. Furthermore, the values of the first 230 s were fitted with a single exponential decay using MATLAB software and the fitted curve was used to calculate the mobile fraction and the recovery time τ . Graphs were made using GraphPad Prism; the line plot shows the mean \pm s.d. and the boxplots divide the data in quartiles. The number of images used for analyses is specified in the figure legends and the significance difference between the central and peripheral adhesions was calculated using the non-parametric Wilcoxon matched-pairs signed rank test (at different time points); *P*-values: ** <0.01 , *** <0.001 .

Flow cytometry and FACS

For FACS analyses, cells were collected after trypsinization, and incubated for 50–60 min with primary and secondary antibodies on ice in PBS

containing 2% FCS. In between the antibody steps, cells were washed twice with 2% FCS in PBS. Finally, cells were passed through a nylon mesh filter and 50000+ cells were analyzed per sample using a FACSCalibur cell analyzer (BD Biosciences). Cells incubated with only secondary antibody were used as a negative control. Graphs include values of a representative experiment (out of three repetitions) normalized to the mode. The graphs were made in FlowJo and adapted in Adobe Illustrator.

Adhesion strengthening assay

To measure long-term adhesion strength of cells, we used the spinning disk assay described by Boettiger (2007). Wild-type or KO HaCaT cells were grown to 60–100% confluence on 30 mm coverslips for 2 days. Just before spinning, the cells were washed briefly with PBS and the coverslips were 'glued' to the stamp using grease. The cells were spun for 8 min at 4240 rpm in PBS-ABC buffer [80% A (10 gl⁻¹ NaCl, 0.25 gl⁻¹ KCl, 0.95 gl⁻¹ Na₂HPO₄*2H₂O, 0.25 gl⁻¹ KH₂PO₄), 10% B (1.34 gl⁻¹ CaCl₂.2H₂O) and 10% C (2 gl⁻¹ MgCl₂.6H₂O)] containing 5% dextran from *Leuconostoc* spp. M, 450,000–600,000 (Sigma-Aldrich). After spinning, the cells were fixed in 2% PFA, permeabilized in 0.2% Triton X-100, stained with DAPI and mounted on microscopic slides using MOWIOL. The complete coverslips were imaged using a Zeiss AxioObserver Z1. The coverslip area was divided in rings with a 1.5 mm diameter and the cell confluence was measured per ring and normalized to the total area of the ring and to the confluence in the middle area (100% confluent). The average shear stress per ring was calculated using the formula $\tau = 10 \times \left(0,8 r \sqrt{\rho\mu\omega^3}\right)$ with τ is the shear stress in dynes/cm², r is the radial distance from the center of rotation in m, ρ is the fluid density in kg m⁻³, μ is the fluid viscosity in Pa s and ω is the rotational velocity in radians min⁻¹. The τ_{50} was obtained by fitting the data points to a logistic function $f = \frac{100}{1 + \exp[(\tau - c)/b]}$ using

MATLAB software, where c is the inflection point and equal to the point of 50% cell detachment (τ_{50}) and b is the slope at the inflection point. Graphs were generated and significance was calculated using GraphPad Prism. The line plots show the mean value of the 9–16 experiments per condition, which are individually shown as squares, diamonds or triangles. For the wild-type line, the same dataset was used in the different graphs. The significance of the percentage of adherent cells in KO cells compared to the wild-type cells was calculated at each data point using unpaired *t*-tests corrected for multiple comparisons using the Holm–Sidak method; *P*-values: ***<0.001, ****<0.0001. The τ_{50} was visualized in a bar graph showing the mean±s.d. of 9–10 independent experiments. The significant different between the τ_{50} in integrin $\beta 4$ KO and integrin $\beta 4$ +CD151 KO cells was calculated using the non-parametric Mann–Whitney *U*-test; *P*-value: ****<0.0001.

Immunoprecipitations and western blotting

For analysis of proteins in whole cell lysates, sub-confluent cells were washed in cold PBS, lysed in RIPA (1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 4 mM EDTA pH 7.5, 100 mM NaCl, 20 mM Tris-HCl pH 7.5) supplemented with inhibitors (1.5 mM Na₃VO₄, 15 mM NaF and 1:500 protease inhibitor cocktail), whole-cell lysates were cleared by centrifugation at 15,000 *g* for 60 min at 4°C and supplemented with SDS sample buffer (50 mM Tris-HCl pH 6.8, 2% SDS, 10% glycerol, 12.5 mM EDTA, 0.02% Bromophenol Blue) with or without β -mercaptoethanol and heated at 95°C for 5 min. Immunoprecipitations were performed with cell lysates prepared in 1% NonidetP-40, 100 mM NaCl, 4 mM EDTA, 20 mM Tris-HCl (pH 7.5), supplemented with inhibitors. After centrifugation at 15,000 *g* for 60 min at 4°C, the cleared lysates were incubated at 4°C for 1.5 h with 1 μ g ml⁻¹ antibody. Subsequently, the lysates were incubated overnight with Protein G Sepharose 4 Fast Flow beads (GE Healthcare), beads were washed three times with lysis buffer and two times with PBS and bound proteins were dissolved in SDS sample buffer without β -mercaptoethanol and heated at 95°C for 5 min.

Proteins were separated on 4–12% bolt Novex gradient gels (Invitrogen) and transferred to Immobilon-P transfer membranes (Millipore). The membrane was blocked for at least 2.5 h in 2% BSA in TBST (10 mM Tris pH 7.5, 150 mM NaCl, 0.05% Tween 20) before incubation with primary antibody overnight at 4°C and with secondary antibody for 1 h at room

temperature. After each incubation, membranes were washed twice with TBST and twice with TBS (TBST without Tween 20). Antibodies were detected using Clarity Western ECL Substrate (Bio-Rad) and in the figures the molecular mass markers (kDa) are indicated.

Acknowledgements

We thank Leila Nahidiazar, Bram van den Broek, Lenny Brooks and Marjolijn Mertz for their help with imaging and image analysis; Martijn van Baalen, Anita Pfauth, Frank van Diepen and Debajit Bhowmick for their help with cell sorting; Alba Zuidema, Veronika Ramovs, Jose de Pereda and Kevin Wilhelmsen for critical reading of the manuscript. Furthermore, we thank our colleagues for sharing reagents.

Competing interests

The authors declare no competing or financial interests.
